13 DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems
14 management and interoperability. Members and non-members may reproduce DMTF specifications and
15 documents, provided that correct attribution is given. As DMTF specifications may be revised from time to
16 time, the particular version and release date should always be noted.

17 Implementation of certain elements of this standard or proposed standard may be subject to third-party
18 patent rights, including provisional patent rights (herein "patent rights"). DMTF makes no representations
19 to users of the standard as to the existence of such rights, and is not responsible to recognize, disclose,
20 or identify any or all such third-party patent right, owners or claimants, nor for any incomplete or
21 inaccurate identification or disclosure of such rights, owners or claimants. DMTF shall have no liability to
22 any party, in any manner or circumstance, under any legal theory whatsoever, for failure to recognize,
23 disclose, or identify any such third-party patent rights, or for such party's reliance on the standard or
24 incorporation thereof in its product, protocols or testing procedures. DMTF shall have no liability to any
25 party implementing such standard, whether such implementation is foreseeable or not, nor to any patent
26 owner or claimant, and shall have no liability or responsibility for costs or losses incurred if a standard is
27 withdrawn or modified after publication, and shall be indemnified and held harmless by any party
28 implementing the standard from any and all claims of infringement by a patent owner for such
29 implementations.

30 For information about patents held by third-parties which have notified the DMTF that, in their opinion,
31 such patent may relate to or impact implementations of DMTF standards, visit

227

Foreword

228 The *Network Controller Sideband Interface (NC-SI) Specification* (DSP0222) was prepared by the PMCI
229 Working Group.

230 This version supersedes version 1.1.0. For a list of changes, see the change log in ANNEX C.

231 DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems
232 management and interoperability.

233 **Acknowledgments**

234 The DMTF acknowledges the following individuals for their contributions to this document:

245

Introduction

246 In out-of-band management environments, the interface between the out-of-band Management Controller
247 and the Network Controller is critical. This interface is responsible for supporting communication between
248 the Management Controller and external management applications. Currently there are multiple such
249 proprietary interfaces in the industry, leading to inconsistencies in implementation of out-of-band
250 management.

251 The goal of this specification is to define an interoperable sideband communication interface standard to
252 enable the exchange of management data between the Management Controller and Network Controller.
253 The Sideband Interface is intended to provide network access for the Management Controller, and the
254 Management Controller is expected to perform all the required network functions.

255 This specification defines the protocol and commands necessary for the operation of the sideband
256 communication interface. This specification also defines physical and electrical characteristics of a
257 sideband binding interface that is a variant of RMIII targeted specifically for sideband communication
258 traffic.

259 The specification is primarily intended for architects and engineers involved in the development of
260 network interface components and Management Controllers that will be used in providing out-of-band
261 management.

262 Network Controller Sideband Interface (NC-SI) Specification

263 1 Scope

264 This specification defines the functionality and behavior of the Sideband Interface responsible for
265 connecting the Network Controller to the Management Controller. It also outlines the behavioral model of
266 the network traffic destined for the Management Controller from the Network Controller.

267 This specification defines the following two aspects of the Network Controller Sideband Interface (NC-SI):

- 268 • behavior of the interface, which include its operational states as well as the states of the
269 associated components
- 270 • the payloads and commands of the communication protocol supported over the interface

271 The scope of this specification is limited to addressing only a single Management Controller
272 communicating with one or more Network Controllers.

273 This specification also defines the following aspects of a 3.3V RMIIB Based Transport (RBT) based
274 physical medium:

- 275 • transport binding for NC-SI over RBT
- 276 • electrical and timing requirements for the RBT
- 277 • an optional hardware arbitration mechanism for RBT

278 Only the topics that may affect the behavior of the Network Controller or Management Controller, as it
279 pertains to the Sideband Interface operations, are discussed in this specification.

309 **3 Terms and definitions**

310 For the purposes of this document, the following terms and definitions apply.

311 **3.1 Requirement term definitions**

312 This clause defines key phrases and words that denote requirement levels in this specification.

313 **3.1**

314 **can**

315 indicates an ability or capability expressed by the specification or of the possibility of some outcome in the
316 context of the specification

317 **3.2**

318 **cannot**

319 indicates the inability or denial of the possibility of a certain outcome in the context of the specification

320 **3.3**

321 **conditional**

322 indicates that an item is required under specified conditions

323 **3.4**

324 **deprecated**

325 indicates that an element or profile behavior has been outdated by newer constructs

326 **3.5**

327 **mandatory**

328 indicates that an item is required under all conditions

329 **3.6**

330 **may**

331 a permission expressed by this specification

- 332 **3.7**
333 **may not**
334 an expression of permission in the negative; a lack of requirement
- 335 **3.8**
336 **not recommended**
337 indicates that valid reasons may exist in particular circumstances when the particular behavior is
338 acceptable or even useful, but the full implications should be understood and carefully weighed before
339 implementing any behavior described with this label
- 340 **3.9**
341 **obsolete**
342 indicates that an item was defined in prior specifications but has been removed from this specification
- 343 **3.10**
344 **optional**
345 indicates that an item is not mandatory, conditional, or prohibited
- 346 **3.11**
347 **recommended**
348 indicates that valid reasons may exist in particular circumstances to ignore a particular item, but the full
349 implications should be understood and carefully weighed before choosing a different course
- 350 **3.12**
351 **required**
352 indicates that the item is an absolute requirement of the specification
- 353 **3.13**
354 **shall**
355 indicates that the item is an absolute requirement of the specification
- 356 **3.14**
357 **shall not**
358 indicates that the item is an absolute prohibition of the specification
- 359 **3.15**
360 **should**
361 indicates a recommendation of the specification, but the full implications should be understood and
362 carefully weighed before choosing a different course
- 363 **3.16**
364 **should not**
365 indicates a recommendation against , but the full implications should be understood and carefully
366 weighed before implementing any behavior described with this label

367 **3.2 NC-SI term definitions**

368 For the purposes of this document, the following terms and definitions apply.

369 **3.2.1**

370 **frame**

371 a data packet of fixed or variable length that has been encoded for digital transmission over a node-to-
372 node link

373 *Frame* is used in references to [IEEE 802.3 Frames](#). *Packet* is used in all other references.

374 **3.2.2**

375 **packet**

376 a formatted block of information carried by a computer network

377 *Frame* is used in references to [IEEE 802.3 Frames](#). *Packet* is used in all other references.

378 **3.2.3**

379 **external network interface**

380 the interface of the Network Controller that provides connectivity to the external network infrastructure;
381 also known as *port*

382 **3.2.4**

383 **internal host interface**

384 the interface of the Network Controller that provides connectivity to the host operating system running on
385 the platform

386 **3.2.5**

387 **Management Controller**

388 an intelligent entity composed of hardware/firmware/software that resides within a platform and is
389 responsible for some or all of the management functions associated with the platform; also known as
390 BMC and Service Processor

391 **3.2.6**

392 **Network Controller**

393 the component within a system that is responsible for providing connectivity to an external Ethernet
394 network

395 **3.2.7**

396 **remote media**

397 a manageability feature that enables remote media devices to appear as if they are attached locally to the
398 host

399 **3.2.8**

400 **Network Controller Sideband Interface**

401 **NC-SI**

402 the interface of the Network Controller that provides network connectivity to a Management Controller;
403 also shown as *Sideband Interface* or *NC-SI* as appropriate in the context

- 404 **3.2.9**
405 **integrated controller**
406 a Network Controller device that supports two or more channels for the NC-SI that share a common
407 NC-SI physical interface (for example, a Network Controller that has two or more physical network ports
408 and a single NC-SI bus connection)
- 409 **3.2.10**
410 **multi-drop**
411 refers to the situation in which multiple physical communication devices share an electrically common bus
412 and a single device acts as the master of the bus and communicates with multiple “slave” or “target”
413 devices
- 414 Related to NC-SI, a Management Controller serves the role of the master, and the Network Controllers
415 are the target devices.
- 416 **3.2.11**
417 **point-to-point**
418 refers to the situation in which only a single Management Controller and single Network Controller
419 package are used on the bus in a master/slave relationship, where the Management Controller is the
420 master
- 421 **3.2.12**
422 **Channel**
423 the control logic and data paths that support NC-SI Pass-through operations through a single network
424 interface (port)
- 425 A Network Controller that has multiple network interface ports can support an equivalent number of NC-SI
426 channels.
- 427 **3.2.13**
428 **Package**
429 one or more NC-SI channels in a Network Controller that share a common set of electrical buffers and
430 common electrical buffer controls for the NC-SI bus
- 431 Typically, a single, logical NC-SI package exists for a single physical Network Controller package (chip or
432 module). However, this specification allows a single physical chip or module to hold multiple NC-SI logical
433 packages.
- 434 **3.2.14**
435 **control traffic**
436 **control packets**
437 command, response, and asynchronous event notification packets transmitted between the Management
438 Controller and Network Controllers for the purpose of managing the NC-SI
- 439 **3.2.15**
440 **Command**
441 control packet sent by the Management Controller to the Network Controller to request the Network
442 Controller to perform an action, and/or return data

443 **3.2.16**444 **Response**

445 control packet sent by the Network Controller to the Management Controller as a positive
446 acknowledgement of a command received from the Management Controller, and to provide the execution
447 outcome of the command, as well as to return any required data

448 **3.2.17**449 **Asynchronous Event Notification**

450 control packet sent by the Network Controller to the Management Controller as an explicit notification of
451 the occurrence of an event of interest to the Management Controller

452 **3.2.18**453 **pass-through traffic**454 **pass-through packets**

455 network packets passed between the external network and the Management Controller through the
456 Network Controller

457 **3.2.19**458 **RBT**459 **RMII-Based Transport**

460 Electrical and timing specification for a 3.3V physical medium that is derived from [RMII](#)

461 **3.3 Numbers and number bases**

462 Hexadecimal numbers are written with a “0x” prefix (for example, 0xFFF and 0x80). Binary numbers are
463 written with a lowercase *b* suffix (for example, 1001b and 10b). Hexadecimal and binary numbers are
464 formatted in the `Courier New` font.

465 **3.4 Reserved fields**

466 Unless otherwise specified, reserved fields are reserved for future use and should be written as zeros and
467 ignored when read.

468 **4 Acronyms and abbreviations**

469 The following symbols and abbreviations are used in this document.

470 **4.1**471 **AC**

536 **5 NC-SI overview**

537 **5.1 General**

538 With the increasing emphasis on out-of-band manageability and functionality, such as Remote Media
539 (R-Media) and Remote Keyboard-Video-Mouse (R-KVM), the need for defining an industry standard
540 Network Controller Sideband Interface (NC-SI) has become clear. This specification enables a common
541 interface definition between different Management Controller and Network Controller vendors. This
542 specification addresses not only the electrical and protocol specifications, but also the system-level
543 behaviors for the Network Controller and the Management Controller related to the NC-SI.

544 The NC-SI is defined as the interface (protocol, messages, and medium) between a Management
545 Controller and one or multiple Network Controllers. This interface, referred to as a Sideband Interface in
546 Figure 1, is responsible for providing external network connectivity for the Management Controller while
547 also allowing the external network interface to be shared with traffic to and from the host.

548 The specification of how the NC-SI protocol and messages are implemented over a particular physical
549 medium is referred to as a transport binding. This document, DSP0222, includes the definition of the
550 transport binding, electrical, framing, and timing specifications for a physical interface called RBT
551 (RMII-based Transport). Electrically, RBT, as described in clause 10, is similar to the Reduced Media
552 Independent Interface™ (RMII) – see ANNEX B. Transport bindings for NC-SI over other media and
553 transport protocols are defined through external transport binding specifications, such as [DSP0261](#), the
554 *NC-SI over MCTP Transport Binding Specification*.

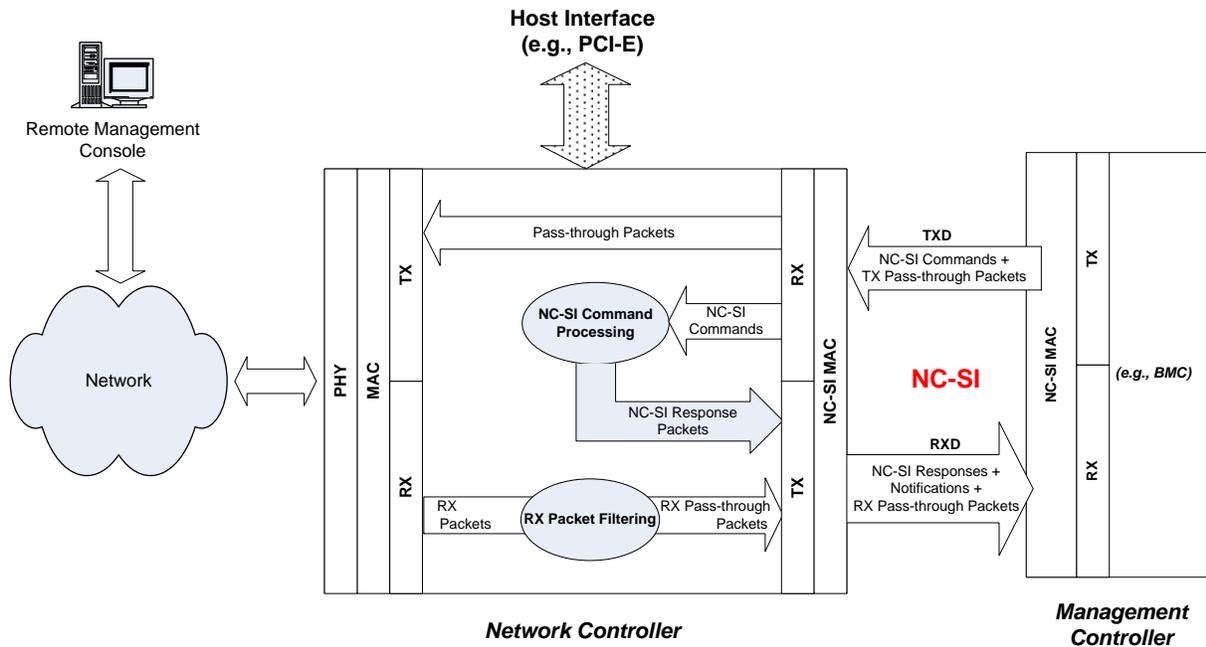

555

556

Figure 1 – NC-SI functional block diagram

557 NC-SI traffic flow is illustrated in Figure 2. Two classes of packet data can be delivered over the Sideband
558 Interface:

- 559 • “Pass-through” packets that are transferred between the Management Controller and the
560 external network
- 561 • “Control” packets that are transferred between the Management Controller and Network
562 Controllers for control or configuration functionality. This specification defines a number of NC-
563 SI commands and responses as well as a mechanism to customize and extend functionality via
564 OEM commands – see ANNEX A.

565

566

Figure 2 – NC-SI traffic flow diagram

567 NC-SI is intended to operate independently from the in-band activities of the Network Controller. As such,
 568 the Sideband Interface is not specified to be accessible through the host interface of the Network
 569 Controller. From the external world, this interface should behave and operate like a standard Ethernet
 570 Interface.

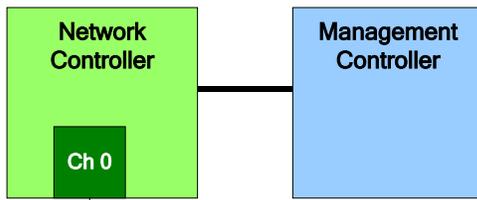

571 **5.2 Defined topologies**

572 The topologies supported under this specification apply to the case in which a single Management
 573 Controller is actively communicating with one or more Network Controllers over NC-SI RBT. The electrical
 574 specification is targeted to directly support up to four physical Network Controller packages. The protocol
 575 specification allows up to eight Network Controller packages, with up to 31 channels per package.

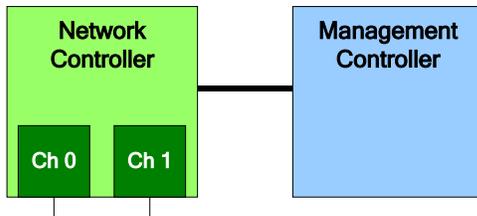

576 Figure 3 illustrates some examples of Network Controller configurations supported by the NC-SI in the
 577 current release:

- 578 • Configuration 1 shows a Management Controller connecting to a single Network Controller with
 579 a single external network connection.
- 580 • Configuration 2 shows a Management Controller connecting to a Network Controller package
 581 that supports two NC-SI channels connections.
- 582 • Configuration 3 shows a Management Controller connecting to four discrete Network
 583 Controllers.

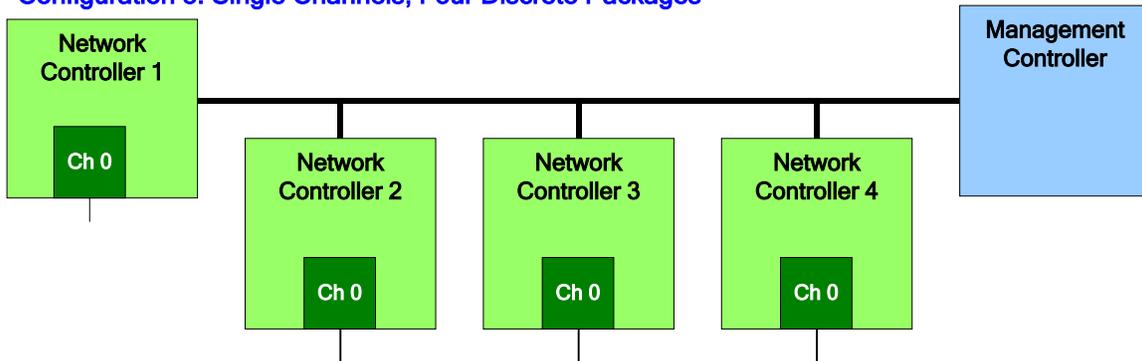

Configuration 1: Single Channel, Single Package

Configuration 2: Integrated Dual Channel, Single Package

Configuration 3: Single Channels, Four Discrete Packages

584

585

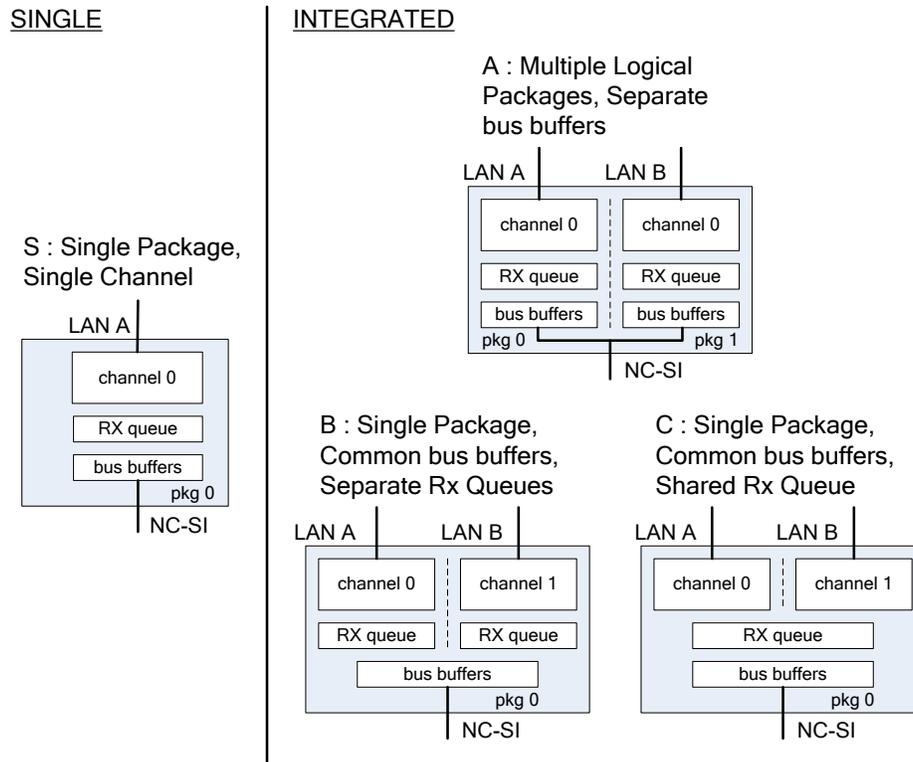

Figure 3 – Example topologies supported by the NC-SI

586 5.3 Single and integrated Network Controller implementations

587 This clause illustrates the general relationship between channels, packages, receive buffers, and bus
588 buffers for different controller implementations.

589 An integrated controller is a Network Controller that connects to the NC-SI and provides NC-SI support for
590 two or more network connections. A single controller is a controller that supports only a single NC-SI
591 channel.

592 For the *NC-SI Specification*, an integrated controller can be logically implemented in one of three basic
593 ways, as illustrated in Figure 4. Although only two channels are shown in the illustration, an integrated
594 controller implementation can provide more than two channels. The example channel and package
595 numbers (for example, channel 0, pkg 0) refer to the Internal Channel and Package ID subfields of the
596 Channel ID. For more information, see 6.2.9.

597

598

Figure 4 – Network Controller integration options

599 Packages that include multiple channels are required to handle internal arbitration between those
 600 channels and the NC-SI. The mechanism by which this occurs is vendor- specific and not specified in this
 601 document. This internal arbitration is always active by default. No NC-SI commands are defined for
 602 enabling or disabling internal arbitration between channels.

603 The following classifications refer to a logical definition. The different implementations are distinguished
 604 by their behavior with respect to the NC-SI bus and command operation. The actual physical and internal
 605 implementation can vary from the simple diagrams. For example, an implementation can act as if it has
 606 separate RX queues without having physically separated memory blocks for implementing those queues.

607 • **S: Single Package, Single Channel**

608 This implementation has a single NC-SI interface providing NC-SI support for a single LAN port,
 609 all contained within a package or module that has a single connection to the NC-SI physical
 610 bus.

611 • **A: Multiple Logical Packages, Separate Bus Buffers**

612 This implementation acts like two physically separate Network Controllers that happen to share
 613 a common overall physical container. Electrically, they behave as if they have separate
 614 electrical buffers connecting to the NC-SI bus. This behavior might be accomplished by means
 615 of a passive internal bus or by separate physical pins coming from the overall package. From
 616 the point of view of the Management Controller and the NC-SI command operation, this
 617 implementation behaves as if the logical controllers were implemented as physically separate
 618 controllers.

619 This type of implementation could include internal hardware arbitration between the two logical
620 Network Controller packages. If hardware arbitration is provided external to the package, it shall
621 meet the requirements for hardware arbitration described later in this specification. (For more
622 information, see 7.3.)

623 • **B: Single Package, Common Bus Buffers, Separate RX Queues**

624 In this implementation, the two internal NC-SI channels share a common set of electrical bus
625 buffers. A single Deselect Package command will deselect the entire package. The Channel
626 Enable and Channel Disable commands to each channel control whether the channel can
627 transmit Pass-through and AEN packets through the NC-SI interface. The Channel Enable
628 command also determines whether the packets to be transmitted through the NC-SI interface
629 will be queued up in an RX Queue for the channel while the channel is disabled or while the
630 package is deselected. Because each channel has its own RX Queue, this queuing can be
631 configured for each channel independently.

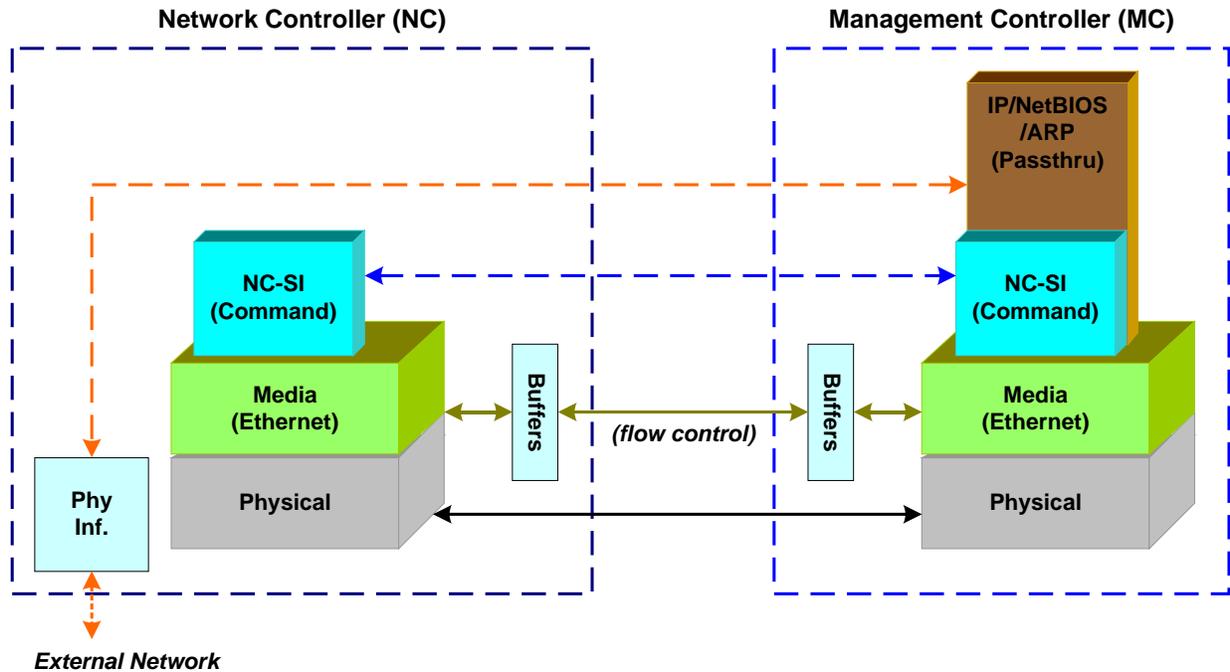

632 • **C: Single Package, Common Bus Buffers, Shared RX Queue**

633 This implementation is the same as described in the preceding implementation, except that the
634 channels share a common RX Queue for holding Pass-through packets to be transmitted
635 through the NC-SI interface. This queue could also queue up AEN or Response packets.

636 5.4 Transport stack

637 The overall transport stack of the NC-SI is illustrated in Figure 5. The lowest level is the physical-level
638 interface (for example, RBT), and the media-level interface is based on Ethernet. Above these interfaces
639 are the two data-level protocols that are supported by the *NC-SI Specification*: NC-SI Command Protocol
640 and the Network Data Protocol (for example, ARP, IP, DHCP, and NetBIOS) associated with Pass-
641 through traffic. Both of these protocols are independent from binding to the underlying physical interface.
642 This specification only defines the binding for NC-SI over RBT.

643 This document defines the necessary NC-SI command set and interface specification that allows the
644 appropriate configuration of the Network Controller parameters and operation to enable network traffic to
645 flow to and from external networks to the Management Controller. As shown in Figure 5 the scope of the
646 NC-SI Command Protocol is limited to the internal interface between the Network Controller and the
647 Management Controller.

648

649

Figure 5 – NC-SI transport stack

650 5.5 Transport protocol

651 A simple transport protocol is used to track the reliable reception of command packets. The transport
 652 protocol is based upon a command/response paradigm and involves the use of unique Instance IDs (IIDs)
 653 in the packet headers to allow responses received to be matched to previously transmitted commands.
 654 The Management Controller is the generator of command packets sent to the Sideband Interface of one
 655 or more Network Controllers in the system, and it receives response packets from them. A response
 656 packet is expected to be received for every command packet successfully sent.

657 The transport protocol described here shall apply only to command and response packets sent between
 658 the Management Controller and the Network Controller.

659 5.6 Byte and bit ordering for transmission

660 Unless otherwise specified, the bytes for a multi-byte numeric field are transmitted most significant byte
 661 first and bits within a byte are transmitted most significant bit first.

662 6 Operational behaviors

663 6.1 Typical operational model

664 This clause describes the typical system-level operation of the NC-SI components.

665 The following tasks are associated with Management Controller use of the NC-SI:

666 • **Initial configuration**

667 When the NC-SI interface is first powered up, the Management Controller needs to discover
 668 and configure NC-SI devices in order to enable pass-through operation. This task includes
 669 setting parameters such as MAC addresses, configuring Layer 2 filtering, setting Channel
 670 enables, and so on.

671 • **Pass-through**

672 The Management Controller handles transmitting and receiving Pass-through packets using the
 673 NC-SI. Pass-through packets can be delivered to and received from the network through the
 674 NC-SI based on the Network Controller’s NC-SI configuration.

675 • **Asynchronous event handling**

676 In certain situations, a status change in the Network Controller, such as a Link State change,
 677 can generate an asynchronous event on the Sideband Interface. These event notifications are
 678 sent to the Management Controller where they are processed as appropriate.

679 • **Error handling**

680 The Management Controller handles errors that could occur during operation or configuration.
 681 For example, a Network Controller might have an internal state change that causes it to enter a
 682 state in which it requires a level of reconfiguration (this condition is called the “Initial State,”
 683 described in more detail in 6.2.4); or a data glitch on the NC-SI could have caused an NC-SI
 684 command to be dropped by the Network Controller, requiring the Management Controller to
 685 retry the command.

686 **6.2 State definitions**

687

688 **6.2.1 General**

689 Table 1 describes states related to whether and when the Network Controller is ready to handle NC-SI
 690 command packets, when it is allowed to transmit packets through the NC-SI interface, and when it has
 691 entered a state where it is expecting configuration by the Management Controller.

692 **Table 1 – NC-SI operating state descriptions**

State	Applies to	Description
Interface Power Down	Package	The NC-SI is in the power down state.
Interface Power Up	Package	The NC-SI is in the power up state, as defined in Clause 10.
Package Selected (also referred to as the Selected state)	Package	A Selected package is allowed to turn on its electrical buffers and transmit through the NC-SI interface.
Package Deselected (also referred to as the Deselected state)	Package	A Deselected package is not allowed to turn on its electrical buffers and transmit through the NC-SI interface.
Hardware Arbitration Enabled	Package	When hardware arbitration is enabled, the package is allowed to transmit through the NC-SI interface only when it is Selected and has the TOKEN op-code.
Hardware Arbitration Disabled	Package	When hardware arbitration is disabled, the package is allowed to transmit through the NC-SI interface anytime that it is Selected, regardless of whether it has the TOKEN op-code.

State	Applies to	Description
Package Ready	Package	In the Package Ready state, the package is able to accept and respond to NC-SI commands for the package and be Selected.
Package Not Ready	Package	The Package Not Ready state is a transient state in which the package does not accept package-specific commands.
Channel Ready	Channel	In the Channel Ready state, a channel within the package is able to accept channel-specific NC-SI commands that are addressed to its Channel ID (Package ID + Internal Channel ID).
Channel Not Ready	Channel	The Channel Not Ready state is a transient state in which the channel does not accept channel-specific commands.
Initial State	Channel	In the Initial State, the channel is able to accept and respond to NC-SI commands, and one or more configuration settings for the channel need to be set or restored by the Management Controller (that is, the channel has not yet been initialized, or has encountered a condition where one or more settings have been lost and shall be restored). Refer to 6.2.4 for more information.
Channel Enabled	Channel	This is a sub-state of the Channel Ready state. When a channel is enabled, the channel is allowed to transmit unrequested packets (that is, packets that are not command responses—for example, AEN and Pass-through packets) through the NC-SI interface whenever the package is Selected.
Channel Disabled	Channel	This is a sub-state of the Channel Ready state. When a channel is disabled, the channel is not allowed to transmit unrequested packets (that is, packets that are not command responses—for example, AEN and Pass-through packets) through the NC-SI interface.

693 6.2.2 NC-SI power states

694 Only two power states are defined for the NC-SI:

- 695 • **NC-SI Interface Power Down state**

696 In this state, the NC-SI Physical interface and the associated receive and transmit buffers in all
697 devices on the NC-SI (that is, the NC-SI interfaces on the Network Controllers and Management
698 Controller) are not powered up.

- 699 • **NC-SI Power Up state**

700 In this state, the NC-SI Physical interface and the associated receive and transmit buffers in all
701 devices on the NC-SI (that is, the Network Controller and Management Controller) are powered
702 up. The Network Controller is expected to transition to the Initial State within T4 seconds after
703 the Power Up state is entered.

704 6.2.3 Package Ready state

705 A Network Controller in the Package Ready state shall be able to respond to any NC-SI commands that
706 are directed to the ID for the overall package (versus being directed to a particular channel within the
707 package). Package-specific commands are identified by a particular set of Channel ID values delivered in
708 the command header (see 6.2.9).

709 6.2.4 Initial State

710 The Initial State for a channel corresponds to a condition in which the NC-SI is powered up and is able to
711 accept NC-SI commands, and the channel has one or more configuration settings that need to be set or
712 restored by the Management Controller. Unless default configuration settings are explicitly defined in this
713 specification, the default values are implementation specific. The MC should not make any assumptions
714 on any configuration settings that are not defined in this specification. Because this state may be entered
715 at any time, the Initial State shall be acknowledged with a Clear Initial State command in order for the
716 Initial State to be exited. This requirement helps to ensure that the Management Controller does not
717 continue operating the interface unaware that the NC-SI configuration had autonomously changed in the
718 Network Controller.

719 An NC-SI channel in the Initial State shall:

720 • be able to respond to NC-SI commands that are directed to the Channel ID for the particular
721 channel (see 6.2.9)

722 • respond to all non-OEM command packets that are directed to the channel with a Response
723 Packet that contains a Response Code of “Command Failed” and a Reason Code of
724 “Initialization Required”

725 NOTE This requirement does not apply to commands that are directed to the overall package, such as
726 the Select Package and Deselect Package commands.

727 • place the channel into the Disabled state

728 • set hardware arbitration (if supported) to “enabled” on Interface Power Up only; otherwise, the
729 setting that was in effect before entry into the Initial State shall be preserved (that is, the
730 hardware arbitration enable/disable configuration is preserved across entries into the Initial
731 State)

732 • set the enabled/disabled settings for the individual MAC and VLAN filters (typically set using the
733 Set MAC Address, Set VLAN Filter, and Enable VLAN commands) to “disabled”

734 NOTE It is recommended that global multicast and broadcast filters are “disabled” in the Initial State.
735 This means that all multicast and broadcast traffic is forwarded to the MC in the Initial State. If the
736 implementation does not have the global multicast or broadcast filters in “disabled” state in the Initial State,
737 the MC might need to explicitly set global multicast and/or broadcast filters prior to enabling receiving
738 pass-through traffic from the NC-SI channel.

739 • reset the counters defined in the Get NC-SI Statistics command and the Get NC-SI Pass-
740 Through Statistics command to 0x0

741 • disable transmission of Pass-through packets onto the network

742 NOTE Upon entry into the Initial State, the Channel Network TX setting is also set to “disabled”.

743 • clear any record of prior command instances received upon entry into the Initial State (that is,
744 assume that the first command received after entering the Initial State is a new command and
745 not a retried command, regardless of any Instance ID that it may have received before entering
746 the Initial State)

747 • disable transmission of AENs

748 Otherwise, there is no requirement that other NC-SI configuration settings be set, retained, or restored to
749 particular values in the Initial State.

750 6.2.5 NC-SI Initial State recovery

751 As described in 6.2.4, a channel in the Initial State shall receive the Clear Initial State command before
752 other commands can be executed. This requirement ensures that if the Initial State is entered

753 asynchronously, the Management Controller is made aware that one or more NC-SI settings may have
754 changed without its involvement, and blocks the Management Controller from issuing additional
755 commands under that condition. Until the channel receives the Clear Initial State command, the
756 Management Controller shall respond to any other received command (except the Select Package and
757 Deselect Package commands) with a Command Failed response code and Interface Initialization
758 Required reason code to indicate that the Clear Initial State command shall be sent. See response and
759 reason code definitions in 8.2.5.

760 NOTE Package commands (for example, Select Package and Deselect Package) are always accepted and
761 responded to normally regardless of whether the Channel is in the Initial State.

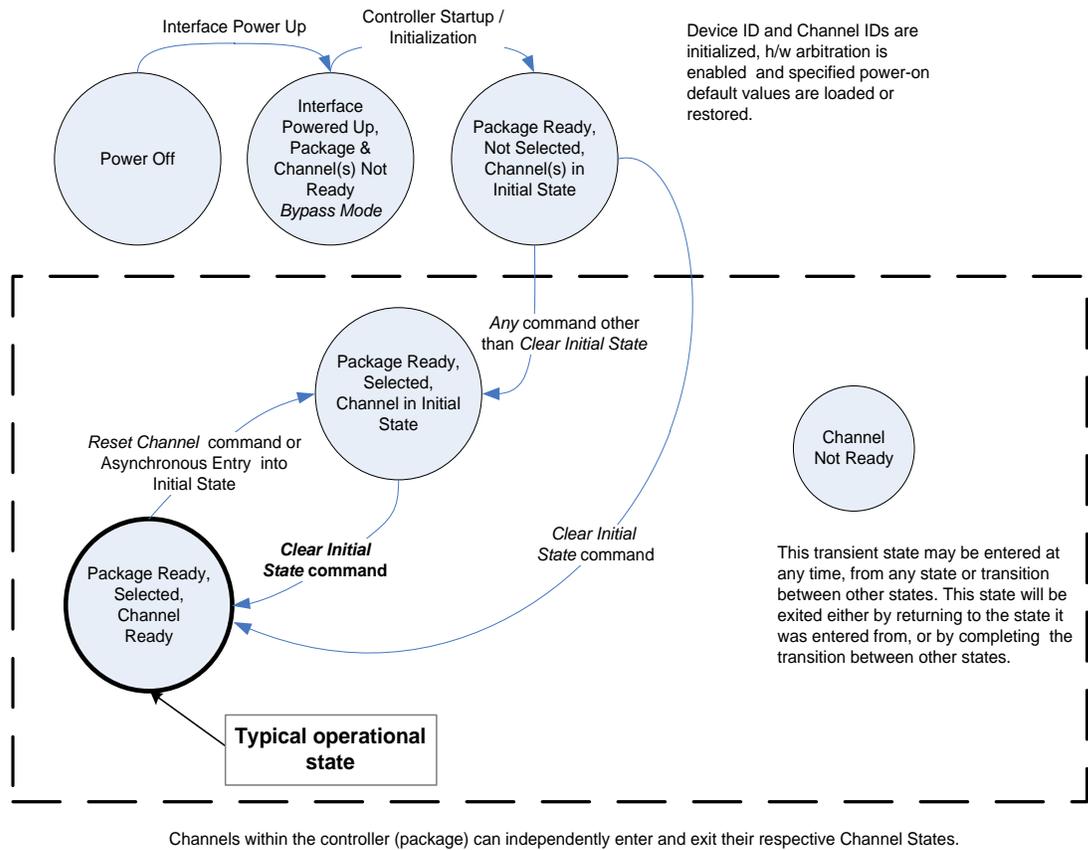

762 If the Management Controller, at any time, receives the response indicating that the Clear Initial State
763 command is expected, it should interpret this response to mean that default settings have been restored
764 for the channel (per the Initial State specification), and that one or more channel settings needs to be
765 restored by the Management Controller.

766 **6.2.6 State transition diagram**

767 Figure 6 illustrates the general relationship between the package- and channel-related states described in
768 Table 1 and the actions that cause transitions between the states. Each bubble in Figure 6 represents a
769 particular combination of states as defined in Table 1.

772 **6.2.7 State diagram for NC-SI operation with hardware arbitration**

773 Figure 7 shows NC-SI operation in the hardware arbitration mode of operation. This is a sub-set of the
 774 general NC-SI operational state diagram (Figure 6) and has been included to illustrate the simplified
 775 sequence of package selection when this optional capability is used.

776

777 **Figure 7 – NC-SI operational state diagram for hardware arbitration operation**

778 While Select and Deselect package commands are not shown in Figure 7, these commands can be used
 779 with the HW arbitration and will behave as specified in this specification.

780 Select and Deselect package commands can work together with HW arbitration. If HW arbitration is
 781 enabled, a package needs both the HW arbitration token and to be selected in order to transmit on the
 782 NC-SI. If either the package is deselected or the package does not have HW arbitration token, then the
 783 package is not allowed to transmit on the NC-SI.

784 6.2.8 Resets**785 6.2.8.1 Asynchronous entry into Initial State**

786 An Asynchronous Reset event is defined as an event that results in a Channel asynchronously entering
787 the Initial State. This event could occur as a consequence of powering up, a System Reset, a Driver
788 Reset, an internal firmware error, loss of configuration errors, internal hardware errors, and so on.

789 Unless otherwise specified, NC-SI configuration settings beyond those required by the Initial State may or
790 may not be preserved following asynchronous entry into the Initial State, depending on the Network
791 Controller implementation.

792 There is no explicit definition of a Reset for an entire package. However, it is possible that an
793 Asynchronous Reset condition may cause an asynchronous entry into the Initial State for all Channels in
794 a package simultaneously.

795 6.2.8.2 Synchronous Reset

796 A Synchronous Reset event on the NC-SI is defined as a Reset Channel command issued by a
797 Management Controller to a Channel. Upon the receipt of this command, the Network Controller shall
798 place the Channel into the Initial State.

799 Unless otherwise specified, NC-SI configuration settings beyond those required by the Initial State may or
800 may not be preserved following a Synchronous Reset, depending on the Network Controller
801 implementation.

802 6.2.8.3 Other Resets

803 Resets that do not affect NC-SI operation are outside the scope of this specification.

804 6.2.9 Network Controller Channel ID

805 Each channel in the Network Controller shall be physically assigned a Network Controller Channel ID that
806 will be used by the Management Controller to specify which Network Controller channel, of possibly
807 many, it is trying to communicate. The Network Controller Channel ID shall be physically assignable
808 (configured) at system-integration time based on the following specification.

809 It is the system integrator's or system designer's responsibility to correctly assign and provide these
810 identifier values in single- and multi-port Network Controller configurations, and to ensure that Channel
811 IDs do not conflict between devices sharing a common NC-SI interconnect.

812 The Channel ID field comprises two subfields, Package ID and Internal Channel ID, as described in Table
813 2 – Channel ID format.

814 Channel IDs shall be completely decoded. Aliasing between values is not allowed (that is, the Network
815 Controller is not allowed to have multiple IDs select the same channel on a given NC-SI).

816

817

Table 2 – Channel ID format

Bits	Field Name	Description
[7..5]	Package ID	<p>The Package ID is required to be common across all channels within a single Network Controller that share a common NC-SI physical interconnect.</p> <p>The system integrator will typically configure the Package IDs starting from 0 and increasing sequentially for each physical Network Controller.</p> <p>The Network Controller shall allow the least significant two bits of this field to be configurable by the system integrator, with the most significant bit of this field = 0b. An implementation is allowed to have all 3 bits configurable.</p>
[4..0]	Internal Channel ID	<p>The Network Controller shall support Internal Channel IDs that are numbered starting from 0 and increasing sequentially for each Pass-through channel supported by the Network Controller that is accessible by the Management Controller through the NC-SI using NC-SI commands.</p> <p>An implementation is allowed to support additional configuration options for the Internal Channel ID as long as the required numbering can be configured.</p> <p>An Internal Channel ID value of 0x1F applies to the entire Package.</p>

818 Once configured, the settings of the Package ID and Internal Channel ID values shall be retained in a
819 non-volatile manner. That is, they shall be retained across power-downs of the NC-SI and shall not be
820 required to be restored by the Management Controller for NC-SI operation. This specification does not
821 define the mechanism for configuring or retaining the Package ID or the Internal Channel ID (if
822 configurable). Some implementations may use pins on the Network Controller for configuring the IDs,
823 other implementations may use non-volatile storage logic such as electrically-erasable memory or
824 FLASH, while others may use a combination of pins and non-volatile storage logic.

825 6.2.10 Configuration-related settings

826 6.2.10.1 Package-specific operation

827 Only two configuration settings are package-specific:

- 828 • the enable/disable settings for hardware arbitration
- 829 • NC-SI flow control

830 Hardware arbitration is enabled or disabled through a parameter that is delivered using the Select
831 Package command. If hardware arbitration is enabled on all Network Controller packages on the NC-SI,
832 more than one package can be in the Selected state simultaneously. Otherwise, only one package is
833 allowed to be in the Selected state at a time in order to prevent electrical buffer conflicts (buffer fights)
834 that can occur from more than one package being allowed to drive the bus.

835 NC-SI flow control is enabled or disabled using the Set NC-SI Flow Control command. The flow control
836 setting applies to all channels in the package.

837 Package-specific commands should only be allowed and executed when the Channel ID field is set to
838 0x1F.

839 6.2.10.2 Channel-specific operation

840 Channel-specific commands should only be allowed to be executed when the Channel ID field is set to a
841 value other than 0x1F. Channel-specific commands with Invalid Channel IDs should not be allowed or
842 executed.

843 Table 3 shows the major categories of configuration settings that control channel operation when a
844 channel is in the Channel Ready state.

845

846

Table 3 – Channel Ready state configuration settings

Setting/Configuration Category	Description
“Channel Enable” settings	The Enable Channel and Disable Channel commands are used to control whether the channel is allowed to asynchronously transmit unrequested packets (AEN and Pass-through packets) through the NC-SI interface whenever the package is Selected. Note that channels are always allowed to transmit responses to commands sent to the channel.
Pass-through Transmit Enable settings	The Enable Channel Network TX command is used to enable the channel to transmit any Pass-through packets that it receives through the NC-SI onto the network, provided that the source MAC address in those packets matches the Network Controller settings. Correspondingly, the Disable Channel Network TX command is used to direct the controller not to transmit Pass-through packets that it receives onto the network.
AEN Enable settings	The AEN Enable command is used to enable and disable the generation of the different AENs supported by the Network Controller.
MAC Address Filter settings and control	The Set MAC Address, Enable Broadcast Filter, and Enable Global Multicast Filter commands are used to configure the filters for unicast, broadcast, and multicast addresses that the controller uses in conjunction with the VLAN Filter settings for filtering incoming Pass-through packets.
VLAN Filter settings and control	The Set VLAN Filter command is used to configure VLAN Filters that the controller uses in conjunction with the MAC Address Filters for filtering incoming Pass-through packets. The Enable VLAN and Disable VLAN commands are used to configure VLAN filtering modes and enable or disable whether VLAN filtering is used.

847 **6.2.11 Transmitting Pass-through packets from the Management Controller**

848 Packets not recognized as command packets (that is, packets without the NC-SI Ethertype) that are
849 received on the Network Controller’s NC-SI interface shall be assumed to be Pass-through packets
850 provided that the source MAC Address matches one of the unicast MAC addresses settings (as
851 configured by the Set MAC Address command) for the channel in the Network Controller, and will be
852 forwarded for transmission to the corresponding external network interface if Channel Network TX is
853 enabled.

854 **6.2.12 Receiving Pass-through packets for the Management Controller**

855 The Management Controller has control over and responsibility for configuring packet-filtering options,
856 such as whether broadcast, multicast, or VLAN packets are accepted. Depending on the filter
857 configurations, after the channel has been enabled, any packet that the Network Controller receives for
858 the Management Controller shall be forwarded to the Management Controller through the NC-SI
859 interface.

860 **6.2.13 Startup sequence examples**

861 **6.2.13.1 Overview**

862 The following clauses show possible startup sequences that may be used by the Management Controller
863 to start NC-SI operation. Depending upon the specific configuration of each system, there are many
864 possible variations of startup sequences that may be used, and these examples are intended for
865 reference only.

866 **6.2.13.2 Typical non hardware arbitration specific startup sequence**

867 The following sequence is provided as an example of one way a Management Controller can start up
868 NC-SI operation. This sequence assumes that the Management Controller has no prior knowledge of how
869 many Network Controllers are hooked to its NC-SI, or what capabilities those controllers support. Note
870 that this is not the only possible sequence. Alternative sequences can also be used to start up NC-SI
871 operation. Some steps may be skipped if the Management Controller has prior knowledge of the Network
872 Controller capabilities, such as whether Network Controllers are already connected and enabled for
873 hardware arbitration.

874 **1) Power up**

875 The NC-SI is powered up (refer to 10.2.7 for the specification of this condition). The Network
876 Controller packages are provided a Device Ready Interval during which they can perform
877 internal firmware startup and initialization to prepare their NC-SI to accept commands. The
878 Management Controller first waits for the maximum Device Ready Interval to expire (refer to
879 Table 118). At this point, all the Network Controller packages and channels should be ready to
880 accept commands through the NC-SI. (The Management Controller may also start sending
881 commands before the Device Ready Interval expires but will have to handle the case that
882 Network Controller devices may be in a state in which they are unable to accept or respond to
883 commands.)

884 **2) Discover package**

885 The Management Controller issues a Select Package command starting with the lowest
886 Package ID (see 8.4.5 for more information). Because the Management Controller is assumed
887 to have no prior knowledge of whether the Network Controller is enabled for hardware
888 arbitration, the Select Package command is issued with the Hardware Arbitration parameter set
889 to 'disable'.

890 If the Management Controller receives a response within the specified response time, it can
891 record that it detected a package at that ID. If the Management Controller does not receive a
892 response, it is recommended that the Management Controller retry sending the command.
893 Three total tries is typical. (This same retry process should be used when sending all
894 commands to the Network Controller and will be left out of the descriptions in the following
895 steps.) If the retries fail, the Management Controller can assume that no Network Controller is at
896 that Package ID and can immediately repeat this step 2) for the next Package ID in the
897 sequence.

898 **3) Discover and get capabilities for each channel in the package**

899 The Management Controller can now discover how many channels are supported in the
900 Network Controller package and their capabilities. To do this, the Management Controller issues
901 the Clear Initial State command starting from the lowest Internal Channel ID (which selects a
902 given channel within a package). If it receives a response, the Management Controller can then
903 use the Get Version ID command to determine NC-SI specification compatibility, and the Get
904 Capabilities command to collect information about the capabilities of the channel. The
905 Management Controller can then repeat this step until the full number of internal channels has

906 been discovered. (The Get Capabilities command includes a value that indicates the number of
907 channels supported within the given package.)

908 NOTE The *NC-SI Specification* requires Network Controllers to be configurable to have their Internal
909 Channel IDs be sequential starting from 0. If it is known that the Network Controller is configured this way,
910 the Management Controller needs only to iterate sequentially starting from Internal Channel
911 ID = 0 up to the number of channels reported in the first Get Capabilities response.

912 The Management Controller should temporarily retain the information from the Get Capabilities
913 command, including the information that reports whether the overall package supports hardware
914 arbitration. This information is used in later steps.

915 **4) Repeat steps 2 and 3 for remaining packages**

916 The Management Controller repeats steps 2) and 3) until it has gone through all the Package
917 IDs.

918 IMPORTANT: Because hardware arbitration has not been enabled yet, the Management
919 Controller shall issue a Deselect Package command to the present Package ID before issuing
920 the Select Package command to the next Package ID. If hardware arbitration is not being used,
921 only one package can be in the Selected state at a time. Otherwise, hardware electrical buffer
922 conflicts (buffer fights) will occur between packages.

923 **5) Initialize each channel in the package**

924 Based on the number of packages and channels that were discovered, their capabilities, and
925 the desired use of Pass-through communication, the Management Controller can initialize the
926 settings for each channel. This process includes the following general steps for each package:

927 a) Issue the Select Package command.

928 b) For each channel in the package, depending on controller capabilities, perform the
929 following actions. Refer to individual command descriptions for more information.

930 • Use the Set MAC Address command to configure which unicast and multicast
931 addresses are used for routing Pass-through packets to and from the Management
932 Controller.

933 • Use the Enable Broadcast Filter command to configure whether incoming broadcast
934 Pass-through packets are accepted or rejected.

935 • Use the Enable Global Multicast Filter command to configure how incoming multicast
936 Pass-through packets are handled based on settings from the Set MAC Address
937 command.

938 • Use the Set VLAN Filter and Enable VLAN Filters commands to configure how
939 incoming Pass-through packets with VLAN Tags are handled.

940 • Use the Set NC-SI Flow Control command to configure how Ethernet Pause Frames
941 are used for flow control on the NC-SI.

942 • Use the AEN Enable command to configure what types of AEN packets the channel
943 should send out on the NC-SI.

944 • Use the Enable Channel Network TX command to configure whether the channel is
945 enabled to deliver Pass-through packets from the NC-SI to the network (based on the
946 MAC address settings) or is disabled from delivering any Pass-through packets to the
947 network.

948 c) Issue the Deselect Package command.

949 6) **Enable hardware arbitration for the packages**

950 If only a single Network Controller package is discovered, the Management Controller does not
951 need to enable hardware arbitration if the controller hardware supports it. In fact, the
952 Management Controller may always elect to disable hardware arbitration, because then it does
953 not need to be concerned with whether the implementation provided a 'loop back' of the
954 hardware arbitration 'ARB_OUT' signal to the controller to the 'ARB_IN' signal.

955 If multiple packages are detected, and each package has reported that it supports hardware
956 arbitration, then the hardware arbitration operation can be enabled by issuing a Select Package
957 command, with the Hardware Arbitration parameter for the command set to 'enabled', to each
958 package. Because hardware arbitration enables multiple packages to be selected
959 simultaneously, sending Deselect Package commands is not necessary when hardware
960 arbitration is being used.

961 NOTE There is no mandatory status to indicate whether hardware arbitration is hooked up and
962 operating correctly. In that case, the Management Controller needs to have prior knowledge that the
963 implementation routes the hardware arbitration signals between the packages.

964 7) **Start Pass-through packet and AEN operation on the channels**

965 The channels should now have been initialized with the appropriate parameters for Pass-
966 through packet reception and AEN operation. Pass-through operation can be started by issuing
967 the Enable Channel command to each channel that is to be enabled for delivering Pass-through
968 packets or generating AENs through the NC-SI interface.

969 If hardware arbitration is not operational and it is necessary to switch operation over to another
970 package, a Deselect Package command shall be issued to the presently selected package
971 before a different package can be selected. Deselecting a package blocks all output from the
972 package. Therefore, it is not necessary to issue Disable Channel commands before selecting
973 another package. There is no restriction on enabling multiple channels within a package.

974

975 **6.2.13.3 Hardware arbitration specific startup sequence**

976 This clause applies when multiple NCs are used by the MC. This clause only applies to the NC-SI over
977 RBT binding.

978 The following is an example of the steps that a Management Controller may perform to start up NC-SI
979 operation when Hardware Arbitration is specifically known to be used, present, and enabled on all
980 Network Controllers. This example startup sequence assumes a high level of integration where the
981 Management Controller knows the Network Controllers support and default to the use of Hardware
982 Arbitration on startup but does not have prior knowledge of how many Network Controllers are interfaced
983 to the NC-SI, or the full set of capabilities those controllers support, so discovery is still required.

984 Although other startup examples may show a specific ordering of steps for the process of discovering,
985 configuring and enabling channels, the Management Controller actually has almost total flexibility in
986 choosing how these steps are performed once a channel in a package is discovered. In the end, it would
987 be just as valid for a Management Controller to follow a breadth-first approach to discovery steps as it
988 would be to follow a depth-first approach where each channel that is discovered is fully initialized and
989 enabled before moving to the next.

990 1) **Power up**

991 No change from other startup scenarios.

992 2) **Discovery**

993 The process of discovery consists of identifying the number of packages that are available, the
994 number of channels that are available in each package, and for each channel, the capabilities
995 that are provided for Management Controller use. Because, in this startup scenario, the
996 Management Controller knows Hardware Arbitration is used, it is not required to use the **Select**
997 **Package** and **Deselect Package** commands for discovery but may elect to just use the **Clear**
998 **Initial State** command for this purpose instead.

999 In this startup scenario, Packages and Channels are discovered by sending the **Clear Initial**
1000 **State** command starting with the lowest Package ID and Channel ID, then waiting for, and
1001 recording, the response event as previously described. Internal channel IDs are required to be
1002 numbered sequentially starting with 0, so when the Management Controller does not receive a
1003 response to repeated attempts at discovery, it knows this means no additional channels exist in
1004 the current package. If this happens when the internal channel ID is 0, the Management
1005 Controller knows a package is not available at the current package ID, and it continues with the
1006 next package ID in sequence. If the Management Controller receives a response to the **Clear**
1007 **Initial State** command, it records that the channel and package are available, and continues
1008 discovery.

1009 During discovery, the Management Controller should interrogate the capabilities of each
1010 channel found to be available in each package by sending the **Get Capabilities** command
1011 appropriate package and channel ID values. However, it does not matter whether this is done
1012 as the very next step in the discovery process or performed for each channel after all packages
1013 and channels have been discovered, just as long as the Management Controller does
1014 interrogate each channel.

1015 3) **Configure each channel and enable pass-through**

1016 Once the existence of all packages and channels, and the capabilities of each channel, have
1017 been discovered and recorded, the Management Controller shall initialize and enable each
1018 channel as needed for use. The details of these steps remain essentially the same as have
1019 been previously stated, except to note that there are no restrictions on how they are performed.
1020 What this means is that the MC may perform these steps in any order across the channels in
1021 each package as it sees fit. The MC may fully initialize and enable each channel in each
1022 package one at a time or perform the same step on each channel in sequence before moving
1023 on to the next, or in a different order. The specific order of steps is not dictated by this
1024 specification.

1025 **6.2.13.4 Summary of scheme for the MC without prior knowledge of hardware arbitration**

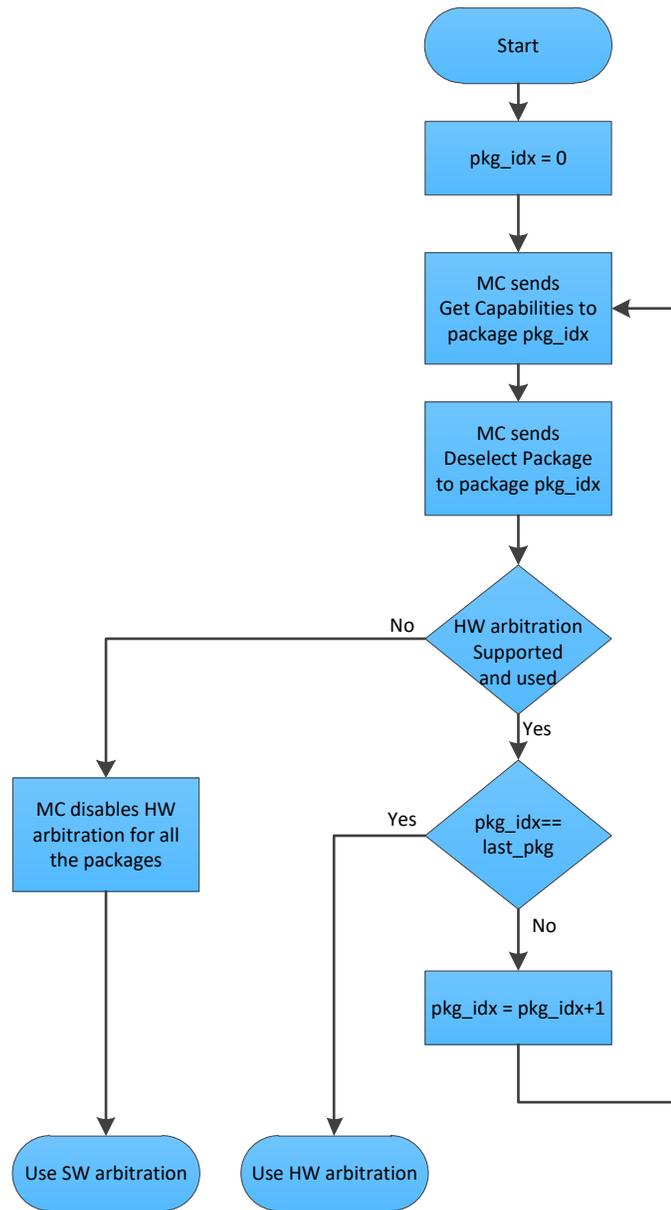

1026 The following scheme describes the case when the MC does not have a priori knowledge of the hardware
1027 arbitration support across multiple NCs.

- 1028 1. For each available NC,
 - 1029 a. The MC checks whether a device supports the HW arbitration, using “**Get Capabilities**”
1030 commands (this implicitly selects the package).
 - 1031 b. The MC issues “**Deselect Package**” for the NC (needed as at this stage we do not know
1032 whether all the devices support HW arbitration).
- 1033 2. If (all NCs support HW arbitration and the HW arbitration is used by all NCs), then
 - 1034 the MC assumes that HW arbitration is active because according to clause 6.2.4 “set
1035 hardware arbitration (if supported) to *enabled* on Interface Power Up only”, and the MC can
1036 “Select” any number of packages at the same time.

1037 Otherwise (at least one NC reports that HW arbitration is not supported, or at least one NC
 1038 reports that HW arbitration is not used, or at least one NC cannot report its support level)

1039 The HW arbitration is **not** active, and the MC can “Select” only single package at the any
 1040 time.

1041 The MC configures each and every NC to disable HW arbitration, using the “**Select**
 1042 **Package**” command.

1043
 1044 **Figure 8 – MC steps when the MC does not have prior knowledge of hardware arbitration**

1045 **6.3 NC-SI traffic types**

1046 **6.3.1 Overview**

1047 Two types of traffic are carried on the NC-SI: Pass-through traffic and Control traffic.

- 1048 • Pass-through traffic consists of packets that are transferred between the external network
1049 interface and the Management Controller using the NC-SI.
- 1050 • Control traffic consists of commands (requests) and responses that support the configuration
1051 and control of the NC-SI and Pass-through operation of the Network Controller, and AENs that
1052 support reporting various events to the Management Controller.

1053 **6.3.2 Command protocol**

1054 **6.3.2.1 Overview**

1055 Commands are provided to allow a Management Controller to initialize, control, and regulate
1056 Management Controller packet flow across the NC-SI, configure channel filtering, and to interrogate the
1057 operational status of the Network Controller. As interface master, the Management Controller is the
1058 initiator of all commands, and the Network Controller responds to commands.

1059 **6.3.2.2 Instance IDs**

1060 The command protocol uses a packet field called the Instance ID (IID). IID numbers are 8-bit values that
1061 shall range from 0x01 to 0xFF. IIDs are used to uniquely identify instances of a command, to improve the
1062 robustness of matching responses to commands, and to differentiate between new and retried
1063 commands. The Network Controller that receives a command handles the IID in the following ways:

- 1064 • It returns the IID value from the command in the corresponding response.
- 1065 • If the IID is the same as the IID for the previous command, it recognizes the command as a
1066 'retried' command rather than as a new instance of the command. It is expected that the 'retried'
1067 command contains the same command type value in the Control Packet Type field. The NC
1068 behavior when a 'retried' command type does not match the original command type is outside
1069 the scope of this specification.
- 1070 • If a retried command is received, the Network Controller shall return the previous response.
1071 Depending on the command, the Network Controller can accomplish this either by holding the
1072 previous response data so that it can be returned, or, if re-executing the command has no side
1073 effects (that is, the command is idempotent), by re-executing the command operation and
1074 returning that response.
- 1075 • When an IID value is received that is different from the one for the previous command, the
1076 Network Controller executes the command as a new command.
- 1077 • When the NC-SI Channel first enters the Initial State, it clears any record of any prior requests.
1078 That is, it assumes that the first command after entering the Initial State is a new command and
1079 not a retried command, regardless of any IID that it may have received before entering the Initial
1080 State.

1081 Thus, for single-threaded operation with idempotent commands, a responding Network Controller can
1082 simply execute the command and return the IID in the response that it received in the command. If it is
1083 necessary to not execute a retried command, the responding controller can use the IID to identify the
1084 retried command and return the response that was delivered for the original command.

1085 The Management Controller that generates a command handles the IID in the following ways:

- 1086 • The IID changes for each new instance of a command.
- 1087 • If a command needs to be retried, the Management Controller uses the same value for the IID
1088 that it used for the initial command.
- 1089 • The Management Controller can optionally elect to use the IID as a way to provide additional
1090 confirmation that the response is being returned for a particular command.

1091 Because an AEN is not a response, an AEN always uses a value of 0x00 for its IID.

1092 NOTE The Instance ID mechanism can be readily extended in the future to support multiple controllers and
1093 multiple outstanding commands. This extension would require having the responder track the IID on a per command
1094 and per requesting controller basis. For example, a retried command would be identified if the IID and command
1095 matched the IID and command for a prior command for the given originating controller's ID. That is, a match is made
1096 with the command, originating controller, and IID fields rather than on the IID field alone. A requester that generates
1097 multiple outstanding commands would correspondingly need to track responses based on both command and IID in
1098 order to match a given response with a given command. IIDs need to be unique for the number of different
1099 commands that can be concurrently outstanding.

1100 6.3.2.3 Single-threaded operation

1101 The Network Controller is required to support NC-SI commands only in a single-threaded manner. That is,
1102 the Network Controller is required to support processing only one command at a time, and is not required
1103 to accept additional commands until after it has sent the response to the previous one.

1104 Therefore, the Management Controller should issue NC-SI commands in a single-threaded manner. That
1105 is, the Management Controller should have only one command outstanding to a given Network Controller
1106 package at a time. Upon sending an NC-SI command packet, and before sending a subsequent
1107 command, the Management Controller should wait for the corresponding response packet to be received
1108 or a command timeout event to occur before attempting to send another command. For the full
1109 descriptions of command timeout, see 6.9.3.2.

1110 6.3.2.4 Responses

1111 The Network Controller shall process and acknowledge each validly formatted command received at the
1112 NC-SI interface by formatting and sending a valid response packet to the Management Controller through
1113 the NC-SI interface.

1114 To allow the Management Controller to match responses to commands, the Network Controller shall copy
1115 the IID number of the Command into the Instance ID field of the corresponding response packet.

1116 To allow for retransmission and error recovery, the Network Controller may re-execute the last command
1117 or maintain a copy of the response packet most recently transmitted to the Management Controller
1118 through its NC-SI interface. This "previous" response packet shall be updated every time a new response
1119 packet is transmitted to the Management Controller by replacing it with the one just sent.

1120 The Network Controller response shall return a "Command Unsupported" response code with an
1121 "Unknown Command Type" reason code for any command (standard or OEM) that the Network Controller
1122 does not support or recognize.

1123 6.3.2.5 Response and post-response processing

1124 Typically, a Network Controller completes a requested operation before sending the response. In some
1125 situations, however, it may be useful for the controller to be allowed to queue up the requested operation
1126 and send the response assuming that the operation will complete correctly (for example, when the
1127 controller is requested to change link configuration). The following provisions support this process:

- 1128 • A Network Controller is allowed to send a response before performing the requested action if
1129 the command is expected to complete normally and all parameters that are required to be
1130 returned with the response are provided.
- 1131 • Temporal ordering of requested operations shall be preserved. For example, if one command
1132 updates a configuration parameter value and a following command reads back that parameter,
1133 the operation requested first shall complete so that the following operation returns the updated
1134 parameter.
- 1135 • Under typical operation of the Network Controller, responses should be delivered within the
1136 Normal Execution Interval (T5) (see Table 118).
- 1137 • Unless otherwise specified, all requested operations shall complete within the Asynchronous
1138 Reset/Asynchronous Not Ready interval (T6) following the response.
- 1139 • If the Network Controller channel determines that the requested operation or configuration
1140 change has not been completed correctly after sending the response, the channel shall enter
1141 the Initial State.

1142 6.3.2.6 NC-SI traffic ordering

1143 This specification does not require any ordering between AENs, NC-SI responses, and NC-SI Pass-
1144 through packets. Specific transport binding specifications may require ordering between AENs, NC-SI
1145 responses, and NC-SI Pass-through packets.

1146 6.4 Link configuration and control

1147 6.4.1.1 Link Configuration

1148 The Network Controller provides commands to allow the Management Controller to specify the
1149 auto-negotiation, link speed, duplex settings, and so on to be used on the network interface. For more
1150 information, see 8.4.21.

1151 6.4.2 The Management Controller should make link configuration changes only when 1152 the host network driver is absent or non-operational. Link Status

1153 The Network Controller provides a Get Link Status command to allow the Management Controller to
1154 interrogate the configuration and operational status of the primary Ethernet links. The Management
1155 Controller may issue the Get Link Status command regardless of OS operational status.

1156 6.5 Frame filtering for Pass-through mode

1157 6.5.1 Overview

1158 The Network Controller provides the option of configuring various types of filtering mechanisms for the
1159 purpose of controlling the delivery of received Ethernet frames to the Management Controller. These
1160 options include VLAN Tag filter, L2 address filters, MAC address support, and limited frame filtering using
1161 L3, L4 protocol header fields. All frames that pass frame filtering are forwarded to the Management
1162 Controller over the NC-SI. Refer to RFC2373, RFC2461 and RFC3315 for IPv6-related definitions.

1163 6.5.2 Multicast filtering

1164 The Network Controller may provide commands to allow the Management Controller to enable and
1165 disable global filtering of all multicast packets. The Network Controller may optionally provide one or more
1166 individual multicast filters, as well as DHCP v6, IPv6 Neighbor Advertisement, IPv6 Router Advertisement,
1167 IPv6 Neighbor Solicitation, and IPv6 MLD filters.

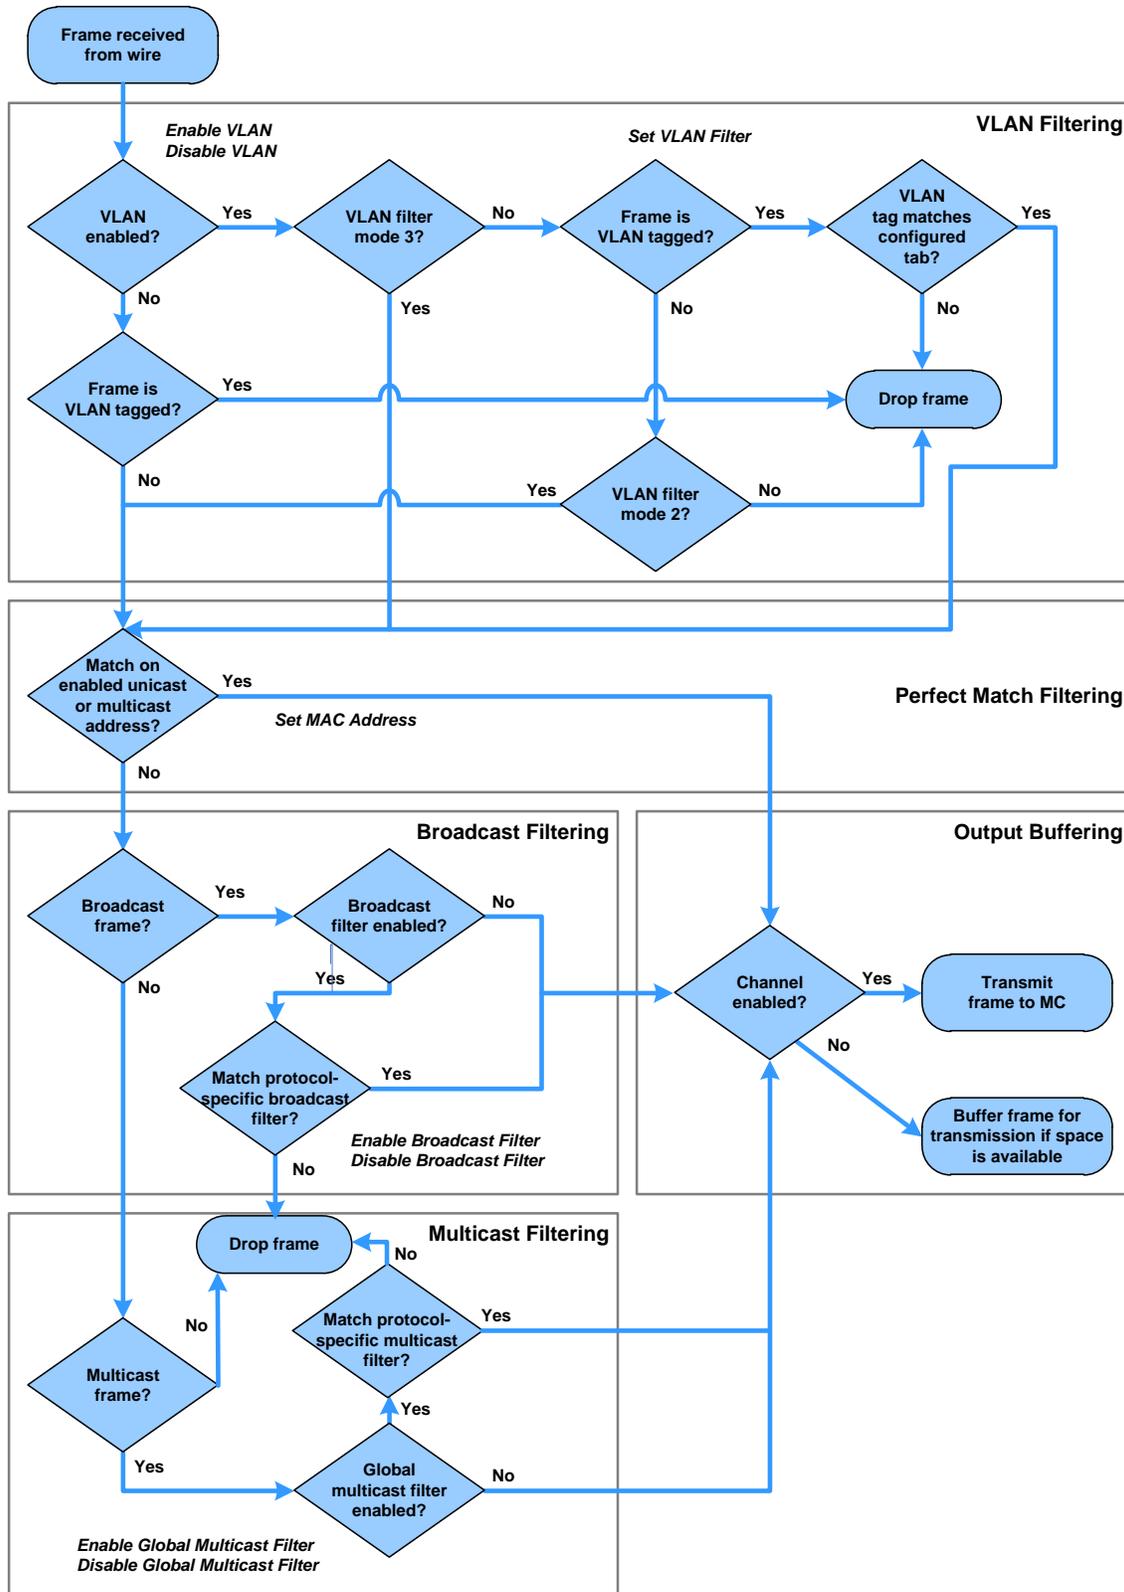

1168 6.5.3 Broadcast filtering

1169 The Network Controller provides commands to allow the Management Controller to enable and disable
1170 forwarding of Broadcast and ARP packets. The Network Controller may optionally support selective
1171 forwarding of broadcast packets for specific protocols, such as DHCP (see RFC2131) and NetBIOS.

1172 6.5.4 VLAN filtering

1173 The Network Controller provides commands to allow the Management Controller to enable and disable
1174 VLAN filtering, configure one or more VLAN Filters, and to configure VLAN filtering modes.

1175 Figure 9 illustrates the flow of frame filtering. Italicized text in the figure is used to identify NC-SI
1176 command names.

1177

1178 **Figure 9 – NC-SI packet filtering flowchart**

1179 **6.6 Output buffering behavior**

1180 There are times when the NC is not allowed to transmit Pass-through, AEN, or control packets onto the
1181 NC-SI.

1182 The NC should buffer Pass-through frames to be transmitted to the MC under any of the following
1183 conditions:

- 1184 • The package is deselected.
- 1185 • For a channel within a package while that channel is disabled.
- 1186 • When the hardware arbitration is enabled and the NC does not have the token to transmit
1187 frames to the MC.

1188 The NC may buffer AENs to the MC under any of the above conditions.

1189 Control packets (responses) are buffered when hardware arbitration is enabled and the NC does not have
1190 the token to transmit frames to the MC.

1191 Additionally, while an NC-SI channel is in the initial state, previously received Pass-through frames and
1192 AENs may or may not be buffered. This behavior is outside the scope of this specification.

1193 **6.7 NC-SI flow control**

1194 The Network Controller may provide commands to enable flow control on the NC-SI between the Network
1195 Controller and the Management Controller. The NC-SI flow control behavior follows the PAUSE frame
1196 behavior as defined in the [IEEE 802.3 specification](#). Flow control is configured using the Set NC-SI Flow
1197 command (see 8.4.41).

1198 **6.8 Asynchronous Event Notification**

1199 Asynchronous Event Notification (AEN) packets enable the Network Controller to deliver unsolicited
1200 notifications to the Management Controller when certain status changes that could impact interface
1201 operation occur in the Network Controller. Because the NC-SI is a small part of the larger Network
1202 Controller, its operation can be affected by a variety of events that occur in the Network Controller. These
1203 events include link status changes, OS driver loads and unloads, and chip resets. This feature defines a
1204 set of notification packets that operate outside of the established command-response mechanism.

1205 Control over the generation of the AEN packets is achieved by control bits in the AEN Enable command.
1206 Each type of notification is optional and can be independently enabled by the Management Controller.

1207 AENs are not acknowledged, and there is no protection against the possible loss of an AEN packet. Each
1208 defined event has its own AEN packet. Because the AEN packets are generated asynchronously by the
1209 Network Controller, they cannot implement some of the features of the other Control packets. AEN
1210 packets leverage the general packet format of Control packets.

- 1211 • The originating Network Controller channel shall fill in its Channel ID (Ch. ID) field in the
1212 command header to identify the source of notification.
- 1213 • The IID field in an AEN shall be set to 0x00 to differentiate it from a response or command
1214 packet.
- 1215 • The Network Controller shall copy the AEN MC ID field from the AEN Enable command into the
1216 MC ID field in every AEN sent to the Management Controller.

1217 **6.9 Error handling**

1218 **6.9.1 Overview**

1219 This clause describes the error-handling methods that are supported over the NC-SI. Two types of error-
1220 handling methods are defined:

- 1221 • Synchronous Error Handling
- 1222 • Errors that trigger Asynchronous Entry into the Initial State

1223 Synchronous Error Handling occurs when an Error (non-zero) Response/Reason Code is received in
1224 response to a command issued by the Management Controller. For information about response and
1225 reason codes, see 8.2.5.

1226 Asynchronous Entry into the Initial State Error Handling occurs when the Network Controller
1227 asynchronously enters the Initial State because of an error condition that affects NC-SI configuration or a
1228 failure of a command that was already responded to. For more information, see 6.2.8.1.

1229 **6.9.2 Transport errors**

1230 **6.9.2.1 Dropped control packets**

1231 The Network Controller shall drop control packets received on the NC-SI interface only under the
1232 following conditions:

- 1233 • The packet has an invalid Frame Check Sequence (FCS) value.
- 1234 • Frame length does not meet [IEEE 802.3](#) requirements (except for OEM commands, where
1235 accepting larger packets may be allowed as a vendor-specific option).
- 1236 • The packet checksum (if provided) is invalid.
- 1237 • The NC-SI Channel ID value in the packet does not match the expected value.
- 1238 • The Network Controller does not have resources available to accept the packet.
- 1239 • The Network Controller receives a command packet with an incorrect header revision.

1240 The Network Controller may also drop control packets if an event that triggers Asynchronous Entry into
1241 the Initial State causes packets to be dropped during the transition.

1242 **6.9.2.2 Pass Through packet errors**

1243 Handling of Pass through packet errors, other than logging statistics, is out of scope of this specification.

1244 **6.9.3 Missing responses**

1245 **6.9.3.1 Overview**

1246 There are typical scenarios in which the Management Controller does not receive the response to a
1247 command:

- 1248 • The Network Controller dropped the command and thus never sent the response.
- 1249 • The response was dropped by the Management Controller (for example, because of a CRC
1250 error in the response packet).
- 1251 • The Network Controller is in the process of being reset or is disabled.

1252 The Management Controller can detect a missing response packet as the occurrence of an NC-SI
1253 command timeout event.

1254 **6.9.3.2 Command timeout**

1255 The Management Controller may detect missing responses by implementing a command timeout interval.
1256 The timeout value chosen by the Management Controller shall not be less than Normal Execution
1257 Interval, T5. Upon detecting a timeout condition, the Management Controller should not make
1258 assumptions on the state of the unacknowledged command (for example, the command was dropped or
1259 the response was dropped), but should retransmit (retry) the previous command using the same IID it
1260 used in the initial command.

1261 The Management Controller should try a command at least three times before assuming an error
1262 condition in the Network Controller.

1263 It is possible that a Network Controller could send a response to the original command at the same time a
1264 retried command is being delivered. Under this condition, the Management Controller could get more than
1265 one response to the same command. Thus, the Management Controller should be capable of determining
1266 that it has received a second instance of a previous response packet. Dropped commands may be
1267 detected by the Management Controller as a timeout event waiting for the response.

1268 **6.9.3.3 Handling dropped commands or missing responses**

1269 To recover from dropped commands or missing responses, the Management Controller can retransmit
1270 the unacknowledged command packet using the same IID that it used for the initial command.

1271 The Network Controller shall be capable of reprocessing retransmitted (retried) commands without error
1272 or undesirable side effects. The Network Controller can determine that the command has been
1273 retransmitted by verifying that the IID is unchanged from the previous command.

1274 **6.9.4 Detecting Pass-through traffic interruption**

1275 The Network Controller might asynchronously enter the Initial State because of a reset or other event. In
1276 this case, the Network Controller stops transmitting Pass-through traffic on the RXD lines. Similarly, Pass-
1277 through traffic sent to the Network Controller may be dropped. If the Management Controller is not in the
1278 state of sending or receiving Pass-through traffic, it may not notice this condition. Thus the Management
1279 Controller should periodically issue a command to the Network Controller to test whether the Network
1280 Controller has entered the Initial State. How often this testing should be done is a choice of the
1281 Management Controller.

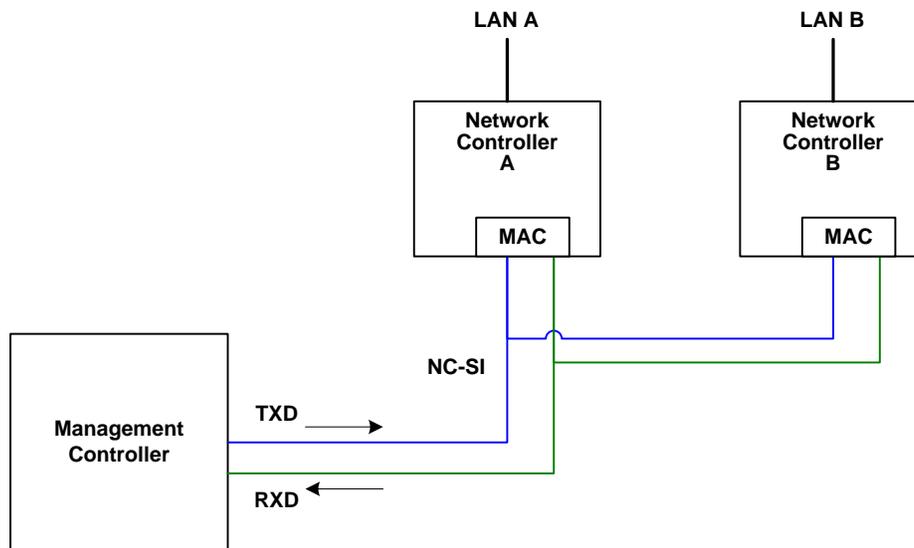

1282 **7 Arbitration in configurations with multiple Network Controller** 1283 **packages**

1284 **7.1 Overview**

1285 This clause applies to NC-SI over RBT only. More than one Network Controller package on a RBT
1286 interface can be enabled for transmitting packets to the Management Controller. This specification
1287 defines two mechanisms to accomplish Network Controller package arbitration operations. One
1288 mechanism uses software commands provided by the Network Controller for the Management Controller
1289 to control whose turn it is to transmit traffic. The other mechanism uses hardware arbitration to share the
1290 single RBT bus. Implementations are required to support command-based Device Selection operation;
1291 the hardware arbitration method is optional.

1292 7.2 Architecture

1293 Figure 10 is a simplified block diagram of the Sideband Interface being used in a multi-drop configuration.
 1294 The RMI (upon which NC-SI is based) was originally designed for use as a point-to-point interconnect.
 1295 Accordingly, only one party can transmit data onto the bus at any given time. There is no arbitration
 1296 protocol intrinsic in the RMI to support managing multiple transmitters.

1297

1298 **Figure 10 – Basic multi-drop block diagram**

1299 However, it is possible for multiple Network Controllers on the interface to be able to simultaneously
 1300 *receive* traffic from the Management Controller that is being transmitted on the NC-SI TXD lines. The
 1301 Network Controllers can receive commands from the Management Controller without having to arbitrate
 1302 for the bus. This facilitates the Management Controller in delivering commands for setup and
 1303 configuration of arbitration.

1304 Arbitration allows multiple Network Controller packages that are attached to the interface to be enabled to
 1305 share the RXD lines to deliver packets to the Management Controller.

1306 This operation is summarized as follows:

- 1307 • Only one Network Controller at a time can transmit packets on the RXD lines of the interface.
- 1308 • Network Controllers can accept commands for configuring and controlling arbitration for the
 1309 RXD lines.

1310 7.3 Hardware arbitration

1311 To prevent two or more NC-SI packages from transmitting at the same time, a hardware-based arbitration
 1312 scheme was devised to allow only one Network Controller package to drive the RX lines of the shared
 1313 interface at any given time. This scheme uses a mechanism of passing messages (op-codes) between
 1314 Network Controller packages to coordinate when a controller is allowed to transmit through the NC-SI
 1315 RBT interface.

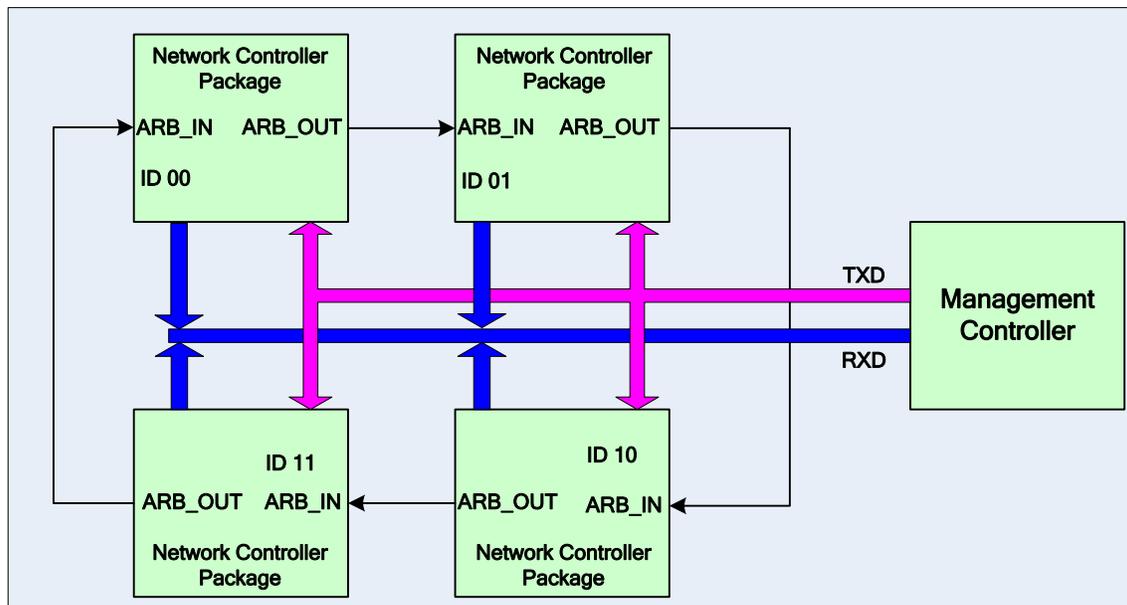

1316 **7.3.1 General**

1317 Three conceptual modes of hardware arbitration exist: arbitration master assignment, normal operation,
 1318 and bypass. After a package is initialized and has its Channel IDs assigned, it enters the arbitration
 1319 master assignment mode. This mode assigns one package the role of an Arbitration Master
 1320 (ARB_Master) that is responsible for initially generating a TOKEN op-code that is required for the normal
 1321 operating mode. In the normal operating mode, the TOKEN op-code is passed from one package to the
 1322 next in the ring. The package is allowed to use the shared RXD signals and transmit if the package has
 1323 received the TOKEN op-code and has a packet to send.

1324 Bypass mode allows hardware arbitration op-codes to pass through a Network Controller package before
 1325 it is initialized. Bypass mode shall be in effect while hardware arbitration is disabled. Bypass mode shall
 1326 be exited and arbitration master assignment mode shall be entered when the hardware arbitration
 1327 becomes enabled or re-enabled.

1328 Hardware-based arbitration requires two additional pins (ARB_IN and ARB_OUT) on the Network
 1329 Controller. The ARB_OUT pin of one package is connected to the ARB_IN pin of the next package to
 1330 form a ring configuration, as illustrated in Figure 11. The timing requirements for hardware arbitration are
 1331 designed to accommodate a maximum of four Network Controller packages. If the implementation
 1332 consists of a single Network Controller package, the ARB_OUT pin may be connected to the ARB_IN pin
 1333 on the same package, or may be left disconnected, in which case hardware arbitration should be disabled
 1334 by using the Select Package command. This specification optionally supports reporting of Hardware
 1335 arbitration implementation status and hardware arbitration status using the **Get Capabilities** command.

1336

1337

1338 **Figure 11 – Multiple Network Controllers in a ring format**

1339 Each Network Controller package sends out pulses on the ARB_OUT pin to create a series of symbols
 1340 that form op-codes (commands) between Network Controllers. Each pulse is one clock wide and

1341 synchronized to REF_CLK. The hardware arbitration data bits follow the same timing specifications used
 1342 for the TXD and RXD data bits (see 10.2.6). The pulses are di-bit encoded to ensure that symbols are
 1343 correctly decoded. The symbols have the values shown in Table 4.

1344 While clause 7.3.2.1 allows for op-code to be truncated, it is recommended that the transmission of
 1345 current op-code on ARB_OUT be completed if the HW arbitration mode is changed in the middle of an
 1346 op-code transfer (or in the middle of a symbol).

1347 **Table 4 – Hardware arbitration di-bit encoding**

Symbol Name	Encoded Value
Esync	11b
Ezero	00b
Eone	01b
Illegal symbol	10b

1348 7.3.2 Hardware arbitration op-codes

1349 The hardware-based arbitration feature has five defined op-codes: IDLE, TOKEN, FLUSH, XON, and
 1350 XOFF. Each op-code starts with an Esync symbol and is followed by either E_{one} or E_{zero} symbols. The
 1351 legal op-codes are listed in Table 5.

1352 **Table 5 – Hardware arbitration op-code format**

Op-Code	Format
IDLE	E _{sync} E _{zero} E _{zero} (110000b)
TOKEN	E _{sync} E _{one} E _{zero} (110100b)
FLUSH	E _{sync} E _{one} E _{one} E _{zero} E(Package_ID[2:0]) E _{zero} (11010100xxxxxx00b)
XOFF	E _{sync} E _{zero} E _{one} E _{zero} E _{zero} E _{zero} (110001000000b)
XON	E _{sync} E _{zero} E _{one} E _{one} E _{zero} E(Package_ID[2:0]) E _{zero} (1100010100uuuuuu00b)

1353 7.3.2.1 Detecting truncated op-codes

1354 A truncated op-code is detected when the number of clocks between E_{sync}s is less than the number of bits
 1355 required for the op-code. Note that any additional bits clocked in after a legitimate op-code is detected do
 1356 not indicate an error condition and are ignored until the next E_{sync}.

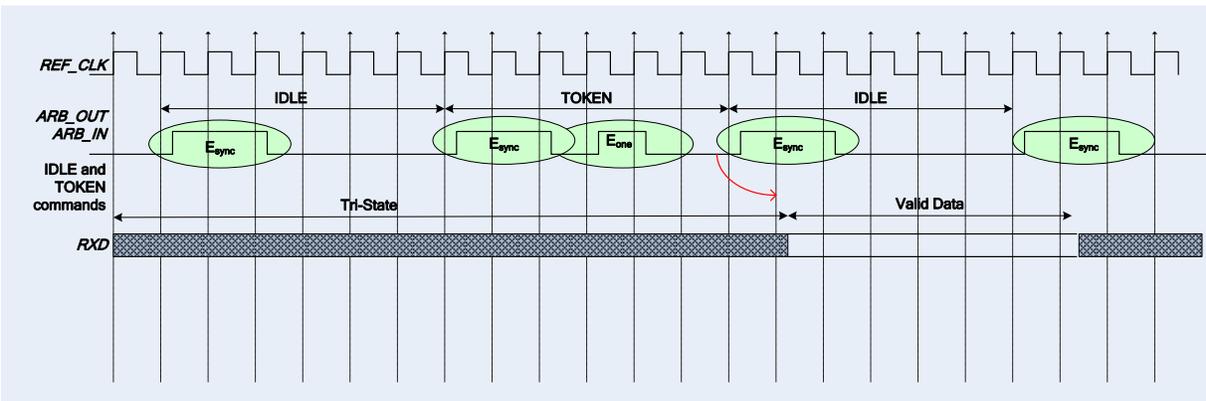

1357 7.3.2.2 Handling truncated or illegal op-codes

1358 When a Network Controller receives a truncated or illegal op-code, it should discard it.

1359 7.3.2.3 Relationship of op-codes processing and driving the RX data lines

1360 A Network Controller package shall take no more than T₉ REF_CLK times after receiving the last bit of
 1361 the op-code to decode the incoming op-code and start generating the outgoing op-code. This time limit
 1362 allows for decoding and processing of the incoming op-code under the condition that an outgoing op-code
 1363 transmission is already in progress.

1364 A package that has received a TOKEN and has packet data to transmit shall turn on its buffer and begin
 1365 transmitting the packet data within T11 REF_CLK times of receiving the TOKEN, as illustrated in
 1366 Figure 12. The package shall disable the RXD buffers before the last clock of the transmitted TOKEN.

1367

1368

Figure 12 – Op-code to RXD relationship

1369 7.3.3 Op-code operations

1370 .

1371 7.3.3.1 TOKEN op-code

1372 When a TOKEN op-code is received, the Network Controller package may drive the RXD signals to send
 1373 only one of the following items: a Pass-through packet, a command response, or an AEN. One [IEEE](#)
 1374 [802.3](#) PAUSE frame (XON or XOFF) may also be sent either before or after one of the previous packets,
 1375 or on its own. While the Network Controller package is transmitting the data on the RXD signals of the
 1376 interface, it shall generate IDLE op-codes on its ARB_OUT pin. Once a package completes its
 1377 transmission, if any, it shall generate and send the TOKEN on its ARB_OUT pin.

1378 7.3.3.2 IDLE op-code

1379 A package that has no other op-code to send shall continuously generate IDLE op-codes. Typically, a
 1380 received IDLE op-code indicates that the TOKEN is currently at another package in the ring. This op-code
 1381 is also used in the ARB_Master assignment process (for details, see 7.3.5).

1382 7.3.3.3 FLUSH op-code

1383 A FLUSH op-code is used to establish an Arbitration Master for the ring when the package enters the
 1384 Package Ready state or when the TOKEN is not received within the specified timeout, T8. This op-code
 1385 is further explained in 7.3.5.

1386 If the package receives a FLUSH op-code while it is in the middle of transmitting a packet onto NC-SI, it
 1387 shall generate IDLE op-codes until the transmission is complete and then process the FLUSH op-code as
 1388 described.

1389 7.3.3.4 Flow Control op-codes

1390 The XON and XOFF op-codes are used to manage the generation of [IEEE 802.3](#) PAUSE frames on =
1391 NC-SI RBT. If the Network Controller supports flow control and flow control is enabled, the XOFF and
1392 XON op-codes behave as described in this clause. If the Network Controller does not support flow control
1393 or if flow control is not enabled, the Network Controller shall pass the op-codes to the next package.

1394 There may be a configuration where some NCs support flow control and others do not. In this
1395 configuration, an NC sending an XOFF op-code may see the XOFF packet emission delayed by two or
1396 more full size Pass-through packets, one for each package not supporting XOFF when it gets the token,
1397 and one for the next package supporting XOFF before sending the XOFF packet. The NC is not required
1398 to provide buffering to prevent packet loss in this configuration. No drop behavior should be expected by
1399 an MC only if all NCs have flow control enabled.

1400 There is a maximum amount of time that the Network Controller is allowed to maintain a PAUSE. For more
1401 information, see 8.4.41.

1402 7.3.3.4.1 XOFF op-code

1403 A Network Controller package that becomes congested while receiving packets from the NC-SI shall
1404 perform the following actions:

- 1405 • If it does not have a TOKEN, it sends the XOFF op-code to the next package.
- 1406 • If it has the TOKEN and has not previously sent an XOFF frame for this instance of congestion,
1407 it shall send a single XOFF frame (PAUSE frame with a pause time of 0xFFFF) and will not
1408 generate an XOFF op-code.
- 1409 • A package may also regenerate an XOFF frame or op-code if it is still congested and
1410 determines that the present PAUSE frame is about to expire.

1411 When a package on the ring receives an XOFF op-code, it shall perform one of the following actions:

- 1412 • If it does not have a TOKEN op-code, it passes the XOFF op-code to the next package in the
1413 ring.
- 1414 • If it has the TOKEN, it shall send an XOFF frame (PAUSE frame with a pause time of 0xFFFF)
1415 and will not regenerate the XOFF op-code. If it receives another XOFF op-code while sending
1416 the XOFF frame or a regular network packet, it discards the received XOFF op-code.

1417 7.3.3.4.2 XON op-code

1418 XON frames (PAUSE frame with a pause time of 0x0000) are used to signal to the Management
1419 Controller that the Network Controller packages are no longer congested and that normal traffic flow can
1420 resume. XON op-codes are used between the packages to coordinate XON frame generation. The
1421 package ID is included in this op-code to provide a mechanism to verify that every package is not
1422 congested before sending an XON frame to the Management Controller.

1423 The XON op-code behaves as follows:

- 1424 • When a package is no longer congested, it generates an XON op-code with its own Package
1425 ID. This puts the package into the 'waiting for its own XON' state.
- 1426 • A package that receives the XON op-code takes one of the following actions:
 - 1427 – If it is congested, it replaces the received XON op-code with the IDLE op-code. This action
1428 causes the XON op-code to be discarded. Eventually, the congested package generates
1429 its own XON op-code when it exits the congested state.

- 1430 – If the package is not congested and is not waiting for the XON op-code with own Package
1431 ID, it forwards the received XON op-code to the next package in the ring.
- 1432 – If the received XON op-code contains the package's own Package ID, the op-code should
1433 be discarded.
- 1434 – If the package is not congested and is waiting for its own XON op-code, it performs one of
1435 the following actions:
- 1436 • If it receives an XON op-code with a Package ID that is higher than its own, it replaces
1437 the XON op-code with its own Package ID.
 - 1438 • If it receives an XON op-code with a Package ID lower than its own, it passes that
1439 XON op-code to the next package and it exits the 'waiting for its own XON' state.
 - 1440 • If it receives an XON op-code with the Package ID equal to its own, it sends an XON
1441 frame on the NC-SI when it receives the TOKEN op-code and exits the 'waiting for its
1442 own XON' state.
- 1443 NOTE More than one XON op-code with the same Package ID can be received while waiting for
1444 the TOKEN and while sending the XON frame. These additional XON op-codes should be discarded.
- 1445 • If a package originates an XON op-code but receives an XOFF op-code, it terminates its XON
1446 request so that it does not output an XON frame when it receives the TOKEN.
- 1447 NOTE This behavior is not likely to occur because the Management Controller will be in the Pause
1448 state at this point.
- 1449 • A package that generated an XON op-code may receive its own XON op-code back while it has
1450 the TOKEN op-code. In this case, it may send a regular packet (Pass-through, command
1451 response, or AEN) to the Management Controller (if it has one to send), an XON frame, or both.

1452 7.3.4 Bypass mode

1453 When the Network Controller package is in bypass mode, data received on the ARB_IN pin is redirected
1454 to the ARB_OUT pin within the specified clock delay. This way, arbitration can continue between other
1455 devices in the ring.

1456 A package in bypass mode shall take no more than $T_{10\text{ REF_CLK}}$ times to forward data from the
1457 ARB_IN pin to the ARB_OUT pin. The transition in and out of bypass mode may result in a truncated
1458 op-code.

1459 A Network Controller package enters into bypass mode immediately upon power up and transitions out of
1460 this mode after the Network Controller completes its startup/initialization sequence.

1461 7.3.5 Hardware arbitration startup

1462 Hardware arbitration startup works as follows:

- 1463 1) All the packages shall be in bypass mode within T_{pwrtz} seconds of NC-SI power up.
- 1464 2) As each package is initialized, it shall continuously generate FLUSH op-codes with its own
1465 Package ID.
- 1466 3) The package then participates in the ARB_MSTR assignment process described in the
1467 following clause.

1468 7.3.6 ARB_MSTR assignment

1469 ARB_MSTR assignment works as follows:

- 1470 1) When a package receives a FLUSH op-code with a Package ID numerically smaller than its
1471 own, it shall forward on the received FLUSH op-code. If the received FLUSH op-code's
1472 Package ID is numerically larger than the local Package ID, the package shall continue to send
1473 its FLUSH op-code with its own Package ID. When a package receives a FLUSH op-code with
1474 its own Package ID, it becomes the master of the ring (ARB_MSTR).
- 1475 2) The ARB_MSTR shall then send out IDLE op-codes until it receives an IDLE op-code.
- 1476 3) Upon receiving the IDLE op-code, the ARB_MSTR shall be considered to be in possession of
1477 the TOKEN op-code (see 7.3.3.1).
- 1478 4) If the package receives a FLUSH op-code while it is in the middle of transmitting a packet onto
1479 NC-SI, it shall generate IDLE op-codes until the transmission is complete and then process the
1480 FLUSH op-code as described.

1481 7.3.7 Token timeout mechanism

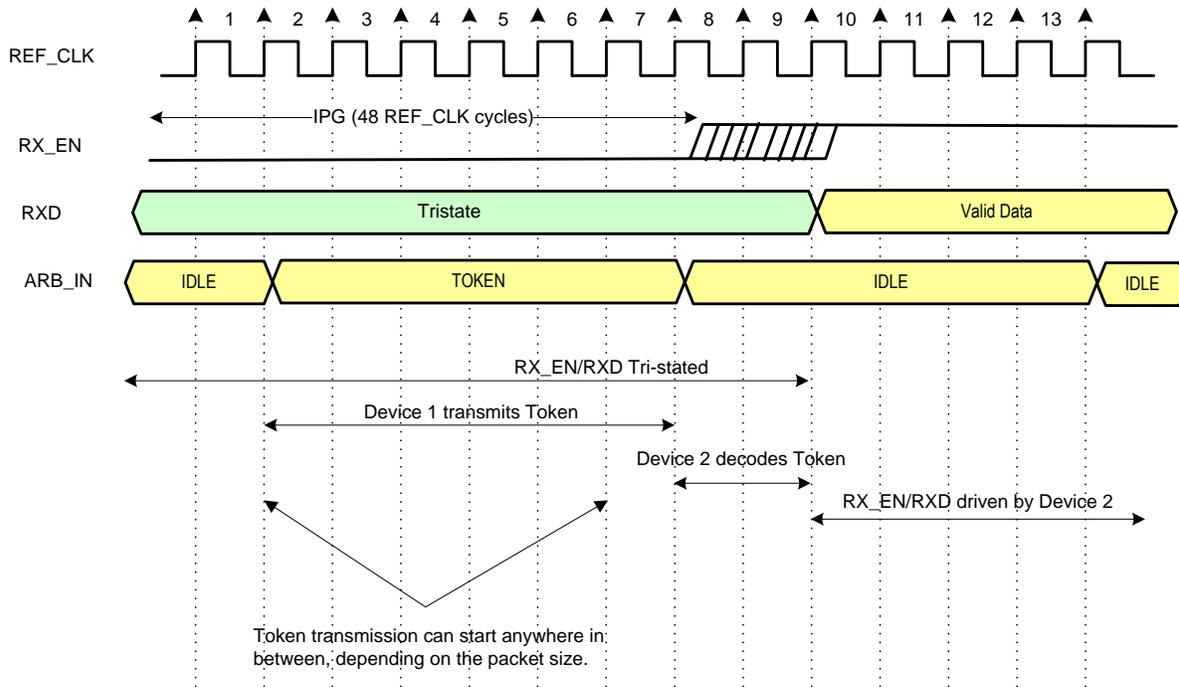

1482 Each Network Controller package that supports hardware-based arbitration control shall implement a
1483 timeout mechanism in case the TOKEN op-code is not received. When a package has a packet to send, it
1484 starts its timer. If it does not receive a TOKEN prior to the TOKEN timeout, the package shall send a
1485 FLUSH op-code. This restarts the arbitration process.

1486 The timer may be programmable depending on the number of packages in the ring. The timeout value is
1487 designed to accommodate up to four packages, each sending the largest packet (1536 bytes) plus
1488 possible XON or XOFF frame transmission and op-code processing time. The timeout shall be no fewer
1489 than T8 cycles of the REF_CLK.

1490 7.3.8 Timing considerations

1491 The ARB_OUT and ARB_IN pins shall follow the timing specifications outlined in Clause 10.

1492 To improve the efficiency of the multi-drop NC-SI, TOKEN op-code generation may overlap the Inter
1493 Packet Gap (IPG) defined by the [802.3](#) specification, as shown in Figure 13. The TOKEN op-code shall
1494 be sent no earlier than the last T13 REF_CLK cycles of the IPG.

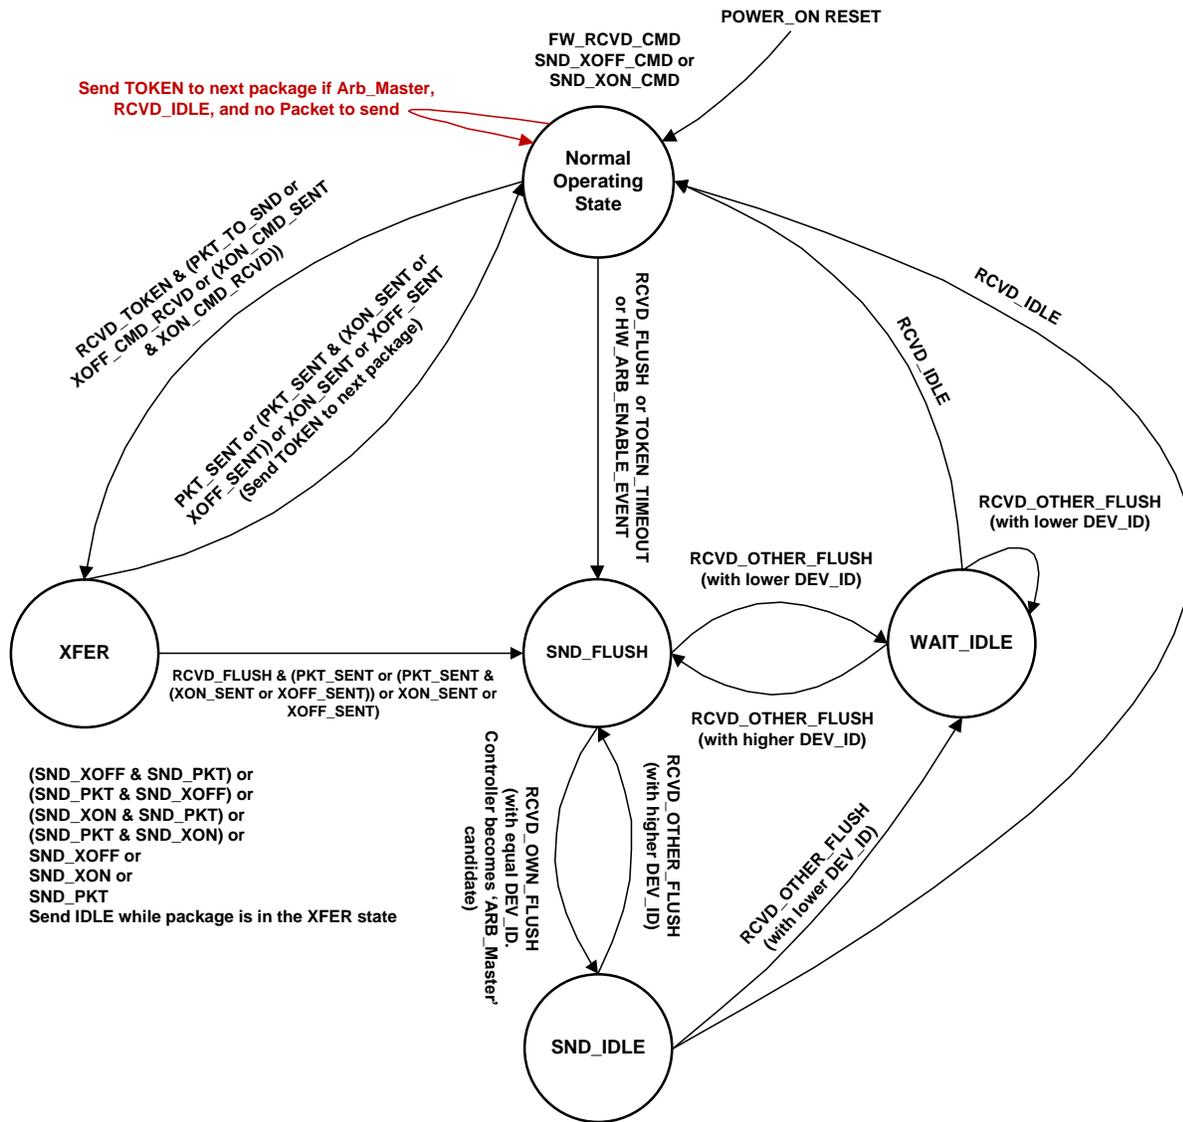

1495

1496

Figure 13 – Example TOKEN to transmit relationship

1497 **7.3.9 Example hardware arbitration state machine**

1498 The state machine diagram shown in Figure 14 is provided as a guideline to help illustrate the startup
 1499 process and op-code operations described in the preceding clauses.

1500

1501

Figure 14 – Hardware arbitration state machine

1502 The states and events shown in Figure 14 are described in Table 6 and Table 7, respectively.

1503 **Table 6 – Hardware arbitration states**

State	Action
Normal Operating State	<p>This state is the normal operating state for hardware arbitration. The following actions happen in this state:</p> <ul style="list-style-type: none"> • FW_RCVD_CMD: Forward received command. As op-codes are received and acted upon, the resulting op-code is sent to the next package. For example, the TOKEN op-code is received and no packet data is available to send, so the TOKEN op-code is sent to the next package in the ring. • SND_XOFF_CMD: Send the XOFF op-code to the next package. This action happens when the specific conditions are met as described in 7.3.3. • SND_XON_CMD: Send the XON op-code to the next package. This action happens when the specific conditions are met as described in 7.3.3. • If the Network Controller is ARB_Master, it generates the TOKEN op-code upon receiving an IDLE op-code at the end of the FLUSH process. • The RXD lines will be in a high-impedance condition in this state.
XFER	<p>In this state, data is sent on the RXD lines. This data will be a Pass-through packet, response packet, XON (Pause Off) packet, XOFF (Pause On) packet, or AEN. (An XON or XOFF packet can be sent in addition to a Pass-through packet, response packet, or AEN.) IDLE op-codes are sent to the next package while the device is in the XFER state.</p> <p>The following actions happen in this state:</p> <ul style="list-style-type: none"> • SND_XON: Transmit an XON frame (Pause Off) to the Management Controller. • SND_XOFF: Transmit an XOFF frame (Pause On) to the Management Controller. • SND_PKT: Transmit a Pass-through packet, response packet, or AEN to the Management Controller. • The TOKEN op-code is sent to the next package upon completion of the transfer.
SND_FLUSH	<p>This state is the entry point for determining the ARB_Master among the packages. In this state, the FLUSH op-code is continuously sent. This state is exited upon receiving a FLUSH op-code that has a DEV_ID that is equal to the package's own DEV_ID.</p>
SND_IDLE	<p>This is the final state for determining the ARB_Master, entered when a device's own FLUSH op-code is received. In this state, the IDLE op-code is continuously sent.</p>
WAIT_IDLE	<p>This state is entered when a FLUSH command is received from another package with a lower Device ID. When an IDLE op-code is received, the ARB_Master has been determined and the device transitions to the Normal Operating State.</p>

1504

Table 7 – Hardware arbitration events

Event	Description
RCVD_TOKEN	A TOKEN op-code was received or the arbitration was just completed and won by this package.
RCVD_IDLE	An IDLE op-code was received.
XOFF_SENT	The Pause On frame was sent on the RXD interface.
XON_SENT	The Pause Off frame was sent on the RXD interface.
PKT_TO_SND	The Network Controller package has a Pass-through packet, command response packet, XON (Pause Off) frame, XOFF (Pause On) frame, or AEN to send.
XON_CMD_RCVD	A package received an XON op-code with its own Package ID.
XOFF_CMD_RCVD	An XOFF op-code was received.
XON_CMD_SENT	A package sent an XON op-code with its own Package ID.
RCVD_FLUSH	A FLUSH op-code was received.
TOKEN_TIMEOUT	The timeout limit expired while waiting for a TOKEN op-code.
HW_ARB_ENABLE_EVENT	This event begins ARB_MSTR assignment. This event occurs just after the Network Controller package initializes or when hardware arbitration is re-enabled through the Select Package command.
RCVD_OTHER_FLUSH	A package received a FLUSH op-code with a Package ID other than its own.
RCVD_OWN_FLUSH	A package received a FLUSH op-code with a Package ID equal to its own.

1505 7.4 Command-based arbitration

1506 If hardware arbitration is not being used, the **Select Package** and **Deselect Package** commands shall be
 1507 used to control which Network Controller package has the ability to transmit on the RXD lines. Because
 1508 only one Network Controller package is allowed to transmit on the RXD lines, the Management Controller
 1509 shall only have one package in the selected state at any given time. For more information, see 8.4.5 and
 1510 8.4.7.

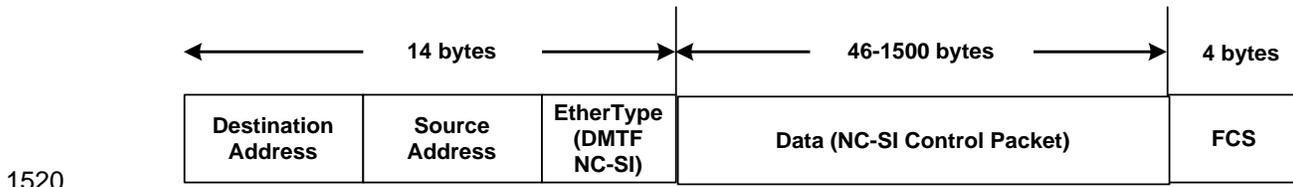

1511 8 Packet definitions

1512 8.1 NC-SI packet encapsulation

1513 The NC-SI is an Ethernet interface adhering to the standard [IEEE 802.3](#) Ethernet frame format. Whether
 1514 or not the Network Controller accepts runt packets is unspecified.

1515 As shown in Figure 15, this L2, or data link layer, frame format encapsulates all NC-SI packets, including
 1516 Pass-through, command, and response packets, as the L2 frame payload data by adding a 14-byte
 1517 header to the front of the data and appending a 4-byte Frame Check Sequence (FCS) to the end.

1518 NC-SI control packets shall not include any VLAN tags. NC-SI Pass-through may include 802.1Q VLAN
 1519 tag.

1521 **Figure 15 – Ethernet frame encapsulation of NC-SI packet data without VLAN tag**

1522 **8.1.1 Ethernet frame header**

1523 The Management Controller shall format the 14-byte Ethernet frame header so that when it is received, it
 1524 shall be formatted in the big-endian byte order shown in Table 8.

1525 Channels shall accept Pass-through packets that meet the [IEEE 802.3](#) frame requirements.

1526 **Table 8 – Ethernet Header Format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..03	DA ₅ = 0xFF	DA ₄ = 0xFF	DA ₃ = 0xFF	DA ₂ = 0xFF
04..07	DA ₁ = 0xFF	DA ₀ = 0xFF	SA ₅	SA ₄
08..11	SA ₃	SA ₂	SA ₁	SA ₀
12..13	EtherType = 0x88F8 (DMTF NC-SI)			

1527 **8.1.1.1 Destination Address (DA)**

1528 Bytes 0–5 of the header represent bytes 5–0 of the Ethernet Destination Address field of an L2 header.

1529 The channel is not assigned a specific MAC address and the contents of this field are not interpreted as a
 1530 MAC address by the Management Controller or the Network Controller. However, the DA field in all NC-SI
 1531 control packets shall be set to the broadcast address (FF:FF:FF:FF:FF:FF) for consistency.

1532 If the Network Controller receives a control packet with a Destination Address other than
 1533 FF:FF:FF:FF:FF:FF, the Network Controller may elect to accept the packet, drop it, or return a response
 1534 packet with an error response/reason code.

1535 **8.1.1.2 Source Address (SA)**

1536 Bytes 6–11 of the header represent bytes 5–0 of the Ethernet Source Address field of the Ethernet
 1537 header. The contents of this field may be set to any value. The Network Controller should use
 1538 FF:FF:FF:FF:FF:FF as the source address for NC-SI Control packets that it generates.

1539 **8.1.1.3 Ethertype**

1540 The final two bytes of the header, bytes 12..13, represent bytes 1..0 of the Ethertype field of the Ethernet
 1541 header. For NC-SI Control packets, this field shall be set to a fixed value of 0x88F8 as assigned to NC-SI
 1542 by the IEEE. This value allows NC-SI Control packets to be differentiated from other packets in the overall
 1543 packet stream.

1544 8.1.2 Frame Check Sequence

1545 The Frame Check Sequence (FCS) shall be added at the end of the frame to provide detection of
1546 corruption of the frame. Any frame with an invalid FCS shall be discarded.

1547 8.1.3 Data length

1548
1549 NC-SI Commands, Responses, and AENs do not carry any VLAN tag. NC-SI Commands, Responses
1550 and AENs shall have a payload data length between 46 and 1500 octets (bytes). This is in compliance
1551 with the 802.3 specification. This means that the length of Ethernet frame shown in Figure 15 is between
1552 64 octets (for a payload of 46 octets) and 1518 octets (for a payload with 1500 octets).
1553

1554 Pass-through packets also follow the 802.3 specification. The maximum payload size is 1500 octets; the
1555 minimum payload size shall be 42 octets when 802.1Q (VLAN) tag is present and 46 octets when the
1556 802.1Q tag is not present. The Layer-2 Ethernet frame for a 802.1Q tagged frame shall be between 64
1557 octets (for a payload of 42 octets) and 1522 octets (for a payload with 1500 octets). For Pass-through
1558 packets that are not 802.1Q tagged, the minimum Layer-2 Ethernet frame size is 64 octets (for a payload
1559 of 46 octets) and the maximum Layer-2 Ethernet frame size is 1518 octets (for a payload with 1500
1560 octets).

1561 8.2 Control packet data structure

1562 Each NC-SI Control packet is made up of a 16-byte packet header and a payload section whose length is
1563 specific to the packet type.

1564 8.2.1 Control packet header

1565 The 16-byte control packet header is used in command, response, and AEN packets, and contains data
1566 values intended to allow the packet to be identified, validated, and processed. The packet header is in
1567 big-endian byte order, as shown in Table 9.

1568 **Table 9 – Control packet header format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..03	MC ID	Header Revision	Reserved	IID
04..07	Control Packet Type	Ch. ID	Reserved	Payload Length
08..11	Reserved			
12..15	Reserved			

1569 8.2.1.1 Management Controller ID

1570 In Control packets, this 1-byte field identifies the Management Controller issuing the packet. For this
1571 version of the specification, Management Controllers should set this field to 0x00 (zero). This implies that
1572 only one management controller is supported for accessing the NC via NC-SI at any given time, Network
1573 Controllers responding to command packets should copy the Management Controller ID field from the
1574 command packet header into the response packet header. For AEN packets, this field should be copied
1575 from the parameter that was set using the AEN Enable command.

1576 8.2.1.2 Header revision

1577 This 1-byte field identifies the version of the Control packet header in use by the sender. For this version
1578 of the specification, the header revision is 0x01.

1579 8.2.1.3 Instance ID (IID)

1580 This 1-byte field contains the IID of the command and associated response. The Network Controller can
1581 use it to differentiate retried commands from new instances of commands. The Management Controller
1582 can use this value to match a received response to the previously sent command. For more information,
1583 see 6.3.2.2.

1584 8.2.1.4 Control packet type

1585 This 1-byte field contains the Identifier that is used to identify specific commands and responses, and to
1586 differentiate AENs from responses. Each NC-SI command is assigned a unique 7-bit command type
1587 value in the range 0x00 . . 0x7F. The proper response type for each command type is formed by setting
1588 the most significant bit (bit 7) in the original 1-byte command value. This allows for a one-to-one
1589 correspondence between 128 unique response types and 128 unique command types.

1590 8.2.1.5 Channel ID

1591 This 1-byte field contains the Network Controller Channel Identifier. The Management Controller shall set
1592 this value to specify the package and internal channel ID for which the command is intended.

1593 In a multi-drop configuration, all commands are received by all NC-SI Network Controllers present in the
1594 configuration. The Channel ID is used by each receiving Network Controller to determine if it is the
1595 intended recipient of the command. In Responses and AENs, this field carries the ID of the channel from
1596 which the response of AEN was issued.

1597 8.2.1.6 Payload length

1598 This 12-bit field contains the length, in bytes, of any payload data present in the command or response
1599 frame following the NC-SI packet header. This value does not include the length of the NC-SI header, the
1600 checksum value, or any padding that might be present.

1601 8.2.1.7 Reserved

1602 These fields are reserved for future use and should be written as zeros and ignored when read.

1603 8.2.2 Control packet payload

1604 The NC-SI packet payload may contain zero or more defined data values depending on whether the
1605 packet is a command or response packet, and on the specific type. The NC-SI packet payload is always
1606 formatted in big-endian byte order, as shown in Table 10.

1607

Table 10 – Generic example of control packet payload

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..03	Data0 ₃	Data0 ₂	Data0 ₁	Data0 ₀
04..07	Data1 ₇	Data1 ₆	Data1 ₅	Data1 ₄
08..11	Data1 ₃	Data1 ₂	Data1 ₁	Data1 ₀
..				
...	DataN-1 ₄	DataN-1 ₃	DataN-1 ₂	DataN-1 ₁
...	DataN-1 ₀	Payload Pad (as required)		
...	2s Complement Checksum Compensation			
...	Ethernet Packet Pad (as required)			

1608 8.2.2.1 Data

1609 As shown in Table 10, the bytes following the NC-SI packet header may contain payload data fields of
 1610 varying sizes, and which may be aligned or require padding. In the case where data is defined in the
 1611 payload, all data-field byte layouts (Data0–Data-1) shall use big-endian byte ordering with the most
 1612 significant byte of the field in the lowest addressed byte position (that is, coming first).

1613 8.2.2.2 Payload pad

1614 If the payload is present and does not end on a 32-bit boundary, one to three padding bytes equal to
 1615 0x00 shall be present to align the checksum field to a 32-bit boundary.

1616 8.2.2.3 2's Complement checksum compensation

1617 This 4-byte field contains the 32-bit checksum compensation value that may be included in each
 1618 command and response packet by the sender of the packet. When it is implemented, the checksum
 1619 compensation shall be computed as the 2's complement of the checksum, which shall be computed as
 1620 the 32-bit unsigned sum of the NC-SI packet header and NC-SI packet payload interpreted as a series of
 1621 16-bit unsigned integer values. A packet receiver supporting packet checksum verification shall use the
 1622 checksum compensation value to verify packet data integrity by computing the 32-bit checksum described
 1623 above, adding to it the checksum compensation value from the packet, and verifying that the result is 0.

1624 Verification of non-zero NC-SI packet checksum values is optional. An implementation may elect to
 1625 generate the checksums and may elect to verify checksums that it receives. The checksum field is
 1626 generated and handled according to the following rules:

- 1627 • A checksum field value of all zeros specifies that a header checksum is not being provided for
 1628 the NC-SI Control packet, and that the checksum field value shall be ignored when processing
 1629 the packet.
- 1630 • If the originator of an NC-SI Control packet is not generating a checksum, the originator shall
 1631 use a value of all zeros for the header checksum field.
- 1632 • If a non-zero checksum field is generated for an NC-SI Control packet, that header checksum
 1633 field value shall be calculated using the specified algorithm.
- 1634 • All receivers of NC-SI Control packets shall accept packets with all zeros as the checksum
 1635 value (provided that other fields and the CRC are correct).

- 1636 • The receiver of an NC-SI Control packet may reject (silently discard) a packet that has an
1637 incorrect non-zero checksum.
- 1638 • The receiver of an NC-SI Control packet may ignore any non-zero checksums that it receives
1639 and accept the packet, even if the checksum value is incorrect (that is, an implementation is not
1640 required to verify the checksum field).
- 1641 • A controller that generates checksums is not required to verify checksums that it receives.
- 1642 • A controller that verifies checksums is not required to generate checksums for NC-SI Control
1643 packets that it originates.

1644 **8.2.2.4 Ethernet packet pad**

1645 Per [IEEE 802.3](#), all Ethernet frames shall be at least 64 bytes in length, from the DA through and
1646 including FCS. For NC-SI packets, this requirement applies to the Ethernet header and payload, which
1647 includes the NC-SI Control packet header and payload. Most NC-SI Control packets are less than the
1648 minimum Ethernet frame payload size of 46 bytes in length and require padding to comply with
1649 [IEEE 802.3](#).

1650 **8.2.3 Command packet payload**

1651 Command packets have no common fixed payload format.

1652 **8.2.4 Response packet payload**

1653 Unlike command packets that do not necessarily contain payload data, all response packets carry at least
1654 a 4-byte payload. This default payload carries the response codes and reason codes (described in 8.2.5)
1655 that provide status on the outcome of processing the originating command packet, and is present in all
1656 response packet payload definitions.

1657 The default payload occupies bytes 00 . . 03 of the response packet payload, with any additional
1658 response-packet-specific payload defined to follow starting on the next word. All response packet payload
1659 fields are defined with big-endian byte ordering, as shown in Table 11.

1660 **Table 11 – Generic example of response packet payload format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..03	Response Code		Reason Code	
..
...	DataN-1 ₄	DataN-1 ₃	DataN-1 ₂	DataN-1 ₁
...	DataN-1 ₀	Word Pad (as required)		
...	2s Complement Checksum Compensation			
...	Ethernet Packet Pad (as required)			

1661 **8.2.5 Response codes and reason codes**1662 **8.2.5.1 General**

1663 Response codes and reason codes are status values that are returned in the responses to NC-SI
 1664 commands. The response code values provide a general categorization of the status being returned. The
 1665 reason code values provide additional detail related to a particular response code.

1666

1667 Response codes and reason codes are divided into numeric ranges that distinguish whether the values
 1668 represent standard codes that are defined in this specification or are vendor/OEM-specific values that are
 1669 defined by the vendor of the controller.

1670 The response code is a 2-byte field where values from 0x00 through 0x7F are reserved for definition by
 1671 this specification. Values from 0x80 through 0xFF are vendor/OEM-specific codes that are defined by the
 1672 vendor of the controller.

1673 The reason code is a 2-byte field. The ranges of values are defined in Table 12.

1674

Table 12 – Reason code ranges

MS-byte	LS-byte	Description
00h	0x00–0x7F	Standard generic reason codes This range of values for the lower byte is used for reason codes that are not specific to a particular command but can be used as reason codes in responses for any command. The values in this range are reserved for definition by this specification.
	0x80–0xFF	Vendor/OEM generic reason codes This range of values for the lower byte is used for reason codes that are not specific to a particular command but can be used as reason codes in responses for any command. Values in this range are defined by the vendor of the controller.
Command Number Note: This means that Command Number 00 cannot have any command-specific reason codes.	0x00–0x7F	Standard command-specific reason codes This range of values for the lower byte is used for reason codes that are specific to a particular command. The upper byte holds the value of the command for which the reason code is defined. The values in this range are reserved for definition by this specification.
	0x80–0xFF	Vendor/OEM command-specific reason codes This range of values for the lower byte is used for reason codes that are specific to a particular command. The upper byte holds the value of the command for which the reason code is defined. Values in this range are defined by the vendor of the controller.

1675 **8.2.5.2 Response code and reason code values**

1676 The standard response code values are defined in Table 13, and the standard reason code values are
 1677 defined in Table 14. Command-specific values, if any, are defined in the clauses that describe the
 1678 response data for the command. Unless otherwise specified, the standard reason codes may be used in
 1679 combination with any response code. There are scenarios where multiple combinations of response and
 1680 reason code values are valid. Unless otherwise specified, an implementation may return any valid
 1681 combination of response and reason code values for the condition.

1682

Table 13 – Standard response code values

Value	Description	Comment
0x0000	Command Completed	Returned for a successful command completion. When this response code is returned, the reason code shall be 0x0000 as described in Table 14.
0x0001	Command Failed	Returned to report that a valid command could not be processed or failed to complete correctly
0x0002	Command Unavailable	Returned to report that a command is temporarily unavailable for execution because the controller is in a transient state or busy condition
0x0003	Command Unsupported	Returned to report that a command is not supported by the implementation. The reason code "Unknown / Unsupported Command Type" should be returned along with this response code for all unsupported commands.
0x8000–0xFFFF	Vendor/OEM-specific	Response codes defined by the vendor of the controller

1683

Table 14 – Standard Reason Code Values

Value	Description	Comment
0x0000	No Error/No Reason Code	When used with the Command Completed response code, indicates that the command completed normally. Otherwise this value indicates that no additional reason code information is being provided.
0x0001	Interface Initialization Required	Returned for all commands except Select/Deselect Package commands when the channel is in the Initial State, until the channel receives a Clear Initial State command
0x0002	Parameter Is Invalid, Unsupported, or Out-of-Range	Returned when a received parameter value is outside of the acceptable values for that parameter
0x0003	Channel Not Ready	May be returned when the channel is in a transient state in which it is unable to process commands normally
0x0004	Package Not Ready	May be returned when the package and channels within the package are in a transient state in which normal command processing cannot be done
0x0005	Invalid payload length	The payload length in the command is incorrect for the given command
0x7FFF	Unknown / Unsupported Command Type	Returned when the command type is unknown or unsupported. This reason code shall only be used when the response code is 0x0003 (Command Unsupported) as described in Table 13.
0x8000–0xFFFF	OEM Reason Code	Vendor-specific reason code defined by the vendor of the controller

1684 8.2.6 AEN packet format

1685 AEN packets shall follow the general packet format of Control packets, with the IID field set to 0 because,
 1686 by definition, the Management Controller does not send a response packet to acknowledge an AEN
 1687 packet. The Control Packet Type field shall have the value 0xFF. The originating Network Controller shall

1688 fill in the Channel ID (Ch. ID) field with its own ID to identify itself as the source of notification. Currently,
 1689 three AEN types are defined in the AEN Type field. Table 15 represents the general AEN packet format.

1690 **Table 15 – AEN packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..03	MC ID = 0x0	0x01	Reserved	IID = 0x0
04..07	Control Packet Type = 0xFF	Originating Ch. ID	Reserved	Payload Length
08..11	Reserved			
12..15	Reserved			
16..19	Reserved			AEN Type
20..23	OPTIONAL AEN Data			
24..27	Checksum			

1691 **8.2.7 AEN packet data structure**

1692 The AEN type field (8-bit) has the values shown in Table 16.

1693 **Table 16 – AEN types**

Value	AEN Type
0x0	Link Status Change
0x1	Configuration Required
0x2	Host NC Driver Status Change
0x3..0x6F	Reserved
0x70..0x7F	Transport-specific AENs
0x80..0xFF	OEM-specific AENs

1694 **8.3 Control packet type definitions**

1695 Command packet types are in the range of 0x00 to 0x7F. Table 17 describes each command, its
 1696 corresponding response, and the type value for each. Table 17 includes commands addressed to either a
 1697 package or a channel. The commands addressed to a package are highlighted with gray background.
 1698 PLDM and OEM-specific commands carried over NC-SI may be package specific or channel specific or
 1699 both.

1700 Mandatory (M), Optional (O), and Conditional (C) refer to command support requirements for the Network
 1701 Controller.

1702

Table 17 – Command and response types

Command Type	Command Name	Description	Response Type	Command Support Requirement
0x00	Clear Initial State	Used by the Management Controller to acknowledge that the Network Controller is in the Initial State	0x80	M
0x01	Select Package	Used to explicitly select a controller package to transmit packets through the NC-SI interface	0x81	M
0x02	Deselect Package	Used to explicitly instruct the controller package to stop transmitting packets through the NC-SI interface	0x82	M
0x03	Enable Channel	Used to enable the NC-SI channel and to cause the forwarding of bidirectional Management Controller packets to start	0x83	M
0x04	Disable Channel	Used to disable the NC-SI channel and to cause the forwarding of bidirectional Management Controller packets to cease	0x84	M
0x05	Reset Channel	Used to synchronously put the Network Controller back to the Initial State	0x85	M
0x06	Enable Channel Network TX	Used to explicitly enable the channel to transmit Pass-through packets onto the network	0x86	M
0x07	Disable Channel Network TX	Used to explicitly disable the channel from transmitting Pass-through packets onto the network	0x87	M
0x08	AEN Enable	Used to control generating AENs	0x88	C
0x09	Set Link	Used during OS absence to force link settings, or to return to auto-negotiation mode	0x89	M
0x0A	Get Link Status	Used to get current link status information	0x8A	M
0x0B	Set VLAN Filter	Used to program VLAN IDs for VLAN filtering	0x8B	M
0x0C	Enable VLAN	Used to enable VLAN filtering of Management Controller RX packets	0x8C	M
0x0D	Disable VLAN	Used to disable VLAN filtering	0x8D	M
0x0E	Set MAC Address	Used to configure and enable unicast and multicast MAC address filters	0x8E	M
0x10	Enable Broadcast Filter	Used to enable selective broadcast packet filtering	0x90	M
0x11	Disable Broadcast Filter	Used to disable all broadcast packet filtering, and to enable the forwarding of all broadcast packets	0x91	M
0x12	Enable Global Multicast Filter	Used to enable selective multicast packet filtering	0x92	C
0x13	Disable Global Multicast Filter	Used to disable all multicast packet filtering, and to enable forwarding of all multicast packets	0x93	C

Command Type	Command Name	Description	Response Type	Command Support Requirement
0x14	Set NC-SI Flow Control	Used to configure IEEE 802.3 flow control on the NC-SI	0x94	O
0x15	Get Version ID	Used to get controller-related version information	0x95	M
0x16	Get Capabilities	Used to get optional functions supported by the NC-SI	0x96	M
0x17	Get Parameters	Used to get configuration parameter values currently in effect on the controller	0x97	M
0x18	Get Controller Packet Statistics	Used to get current packet statistics for the Ethernet Controller	0x98	O
0x19	Get NC-SI Statistics	Used to request the packet statistics specific to the NC-SI	0x99	O
0x1A	Get NC-SI Pass-through Statistics	Used to request NC-SI Pass-through packet statistics	0x9A	O
0x1B	Get Package Status	Used to get current status of the package.	0x9B	O
0x50	OEM Command	Used to request vendor-specific data	0xD0	O
0x51	PLDM	Used for PLDM request over NC-SI over RBT	0xD1	O
0x52	Get Package UUID	Returns a universally unique identifier (UUID) for the package	0xD2	O
0x51–0x60	Reserved for Transport Protocol Specific Commands	Used to define transport protocol specific commands (e.g., PLDM over NC-SI/RBT)	0xD1–0xE0	O

Key: M = Mandatory (required)
 O = Optional
 C = Conditional (see command description)

1703 **8.4 Command and response packet formats**

1704 This clause describes the format for each of the NC-SI commands and corresponding responses.

1705 The corresponding response packet format shall be mandatory when a given command is supported.

1706 **8.4.1 NC-SI command frame format**

1707 Table 18 illustrates the NC-SI frame format that shall be accepted by the Network Controller.

1708 **Table 18 – Example of complete minimum-sized NC-SI command packet**

Bytes	Bits

1712 **8.4.3 Clear Initial State command (0x00)**

1713 The Clear Initial State command provides the mechanism for the Management Controller to acknowledge
 1714 that it considers a channel to be in the Initial State (typically because the Management Controller received
 1715 an “Interface Initialization Required” reason code) and to direct the Network Controller to start accepting
 1716 commands for initializing or recovering the NC-SI operation. When in the Initial State, the Network
 1717 Controller shall return the “Interface Initialization Required” reason code for all commands until it receives
 1718 the Clear Initial State command.

1719 If the channel is in the Initial State when it receives the Clear Initial State command, the command shall
 1720 cause the Network Controller to stop returning the “Interface Initialization Required” reason code. The
 1721 channel shall also treat any subsequently received instance ID numbers as IDs for new command
 1722 instances, not retries.

1723 If the channel is not in the Initial State when it receives this command, it shall treat any subsequently
 1724 received instance ID numbers as IDs for new command instances, not retries.

1725 Table 20 illustrates the packet format of the Clear Initial State command.

1726 **Table 20 – Clear Initial State command packet format**

24..45	Pad			

1730 8.4.5 Select Package command (0x01)

1731 A package is considered to be “selected” when its NC-SI output buffers are allowed to transmit packets
1732 through the NC-SI interface. Conversely, a package is “deselected” when it is not allowed to transmit
1733 packets through the NC-SI interface.

1734 The Select Package command provides a way for a Management Controller to explicitly take a package
1735 out of the deselected state and to control whether hardware arbitration is enabled for the package.
1736 (Similarly, the Deselect Package command allows a Management Controller to explicitly deselect a
1737 package.)

1738 The NC-SI package in the Network Controller shall also become selected if the package receives any
1739 other NC-SI command that is directed to the package or to a channel within the package.

1740 The Select Package command is addressed to the package, rather than to a particular channel (that is,
1741 the command is sent with a Channel ID where the Package ID subfield matches the ID of the intended
1742 package and the Internal Channel ID subfield is set to 0x1F).

1743 More than one package can be in the selected state simultaneously if hardware arbitration is used
1744 between the selected packages and is active. The hardware arbitration logic ensures that buffer conflicts
1745 will not occur between selected packages.

1746 If hardware arbitration is not active or is not used for a given package, only one package shall be selected
1747 at a time. To switch between packages, the Deselect Package command is used by the Management
1748 Controller to put the presently selected package into the deselected state before another package is
1749 selected.

1750 A package shall stay in the selected state until it receives a Deselect Package command, unless an
1751 internal condition causes all internal channels to enter the Initial State.

1752 A package that is not using hardware arbitration may leave its output buffers enabled for the time that it is
1753 selected, or it may place its output buffers into the high-impedance state between transmitting packets
1754 through the NC-SI interface. (Temporarily placing the output buffers into the high-impedance state is not
1755 the same as entering the deselected state.)

1756 For Type A integrated controllers: Because the bus buffers are separately controlled, a separate Select
1757 Package command needs to be sent to each Package ID in the controller that is to be enabled to transmit
1758 through the NC-SI interface. If the internal packages do not support hardware arbitration, only one
1759 package shall be selected at a time; otherwise, a bus conflict will occur.

1760 For Type S single channel, and Types B and C integrated controllers: A single set of bus buffers exists for
1761 the package. Sending a Select Package command selects the entire package and enables all channels
1762 within the package to transmit through the NC-SI interface. (Whether a particular channel in a selected
1763 package starts transmitting Pass-through and AEN packets depends on whether that channel was
1764 enabled or disabled using the Enable or Disable Channel commands and whether the package may have
1765 had packets queued up for transmission.)

1766 Table 22 illustrates the packet format of the Select Package command. Table 23 illustrates the disable
1767 byte for hardware arbitration.

1768

Table 22 – Select Package command packet format

Bits

1769

Table 23 – Hardware arbitration disable byte

Bits	Description
0	<p>0b = Hardware arbitration between packages is enabled.</p> <p>1b = Disable hardware arbitration. Disabling hardware arbitration causes the package's arbitration logic to enter or remain in bypass mode.</p> <p>In the case that the Network Controller does not support hardware arbitration, this bit is ignored; the Network Controller shall not return an error if the Select Package command can otherwise be successfully processed.</p>
7..1	Reserved

1770 8.4.6 Select package response (0x81)

1771 Currently no command-specific reason code is identified for this response (see Table 24).

1772

Table 24 – Select package response packet format

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

1773 8.4.7 Deselect Package command (0x02)

1774 The Deselect Package command directs the controller package to stop transmitting packets through the
1775 NC-SI interface and to place the output buffers for the package into the high-impedance state.

1776 The Deselect Package command is addressed to the package, rather than to a particular channel (that is,
1777 the command is sent with a Channel ID where the Package ID subfield matches the ID of the intended
1778 package and the Internal Channel ID subfield is set to 0x1F).

1779 The controller package enters the deselected state after it has transmitted the response to the Deselect
1780 Package command and placed its buffers into the high-impedance state. The controller shall place its
1781 outputs into the high-impedance state within the Package Deselect to Hi-Z Interval (T1). (This interval

1782 gives the controller being deselected time to turn off its electrical output buffers after sending the
 1783 response to the Deselect Package command.)

1784 If hardware arbitration is not supported or used, the Management Controller should wait for the Package
 1785 Deselect to Hi-Z Interval (T1) to expire before selecting another controller.

1786 For Type A integrated controllers: Because the bus buffers are separately controlled, putting the overall
 1787 controller package into the high-impedance state requires sending separate Deselect Package
 1788 commands to each Package ID in the overall package.

1789 For Type S single channel, and Types B and C integrated controllers: A single set of bus buffers exists for
 1790 the package. Sending a Deselect Package command deselects the entire NC-SI package and prevents
 1791 all channels within the package from transmitting through the NC-SI interface.

1792 Table 25 illustrates the packet format of the Deselect Package command.

1793 **Table 25 – Deselect Package command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

1794 **8.4.8 Deselect Package response (0x82)**

1795 The Network Controller shall always put the package into the deselected state after sending a Deselect
 1796 Package Response.

1797 No command-specific reason code is identified for this response (see Table 26).

1798 **Table 26 – Deselect Package response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00

20..23		Checksum			
24..45		Pad			

1807 **8.4.11 Disable Channel command (0x04)**

1808 The Disable Channel command allows the Management Controller to disable the flow of packets,
1809 including Pass-through and AEN, to the Management Controller.

1810 A Network Controller implementation is not required to flush pending packets from its RX Queues when a
1811 channel becomes disabled. If queuing is subsequently disabled for a channel, it is possible that a number
1812 of packets from the disabled channel could still be pending in the RX Queues. These packets may
1813 continue to be transmitted through the NC-SI interface until the RX Queues are emptied of those packets.
1814 The Management Controller should be aware that it might receive a number of packets from the channel
1815 before receiving the response to the Disable Channel command.

1816 The 1-bit Allow Link Down (ALD) field can be used by the Management Controller to indicate that the link
1817 corresponding to the specified channel is not required after the channel is disabled. The Network
1818 Controller is allowed to take down the external network physical link if no other functionality (for example,
1819 host OS or WoL [Wake-on-LAN]) is active.

1820 Possible values for the 1-bit ALD field are as follows:

- 1821
- 0b = Keep link up (establish and/or keep a link established) while channel is disabled
 - 1b = Allow link to be taken down while channel is disabled
- 1822

1823 Table 29 illustrates the packet format of the Disable Channel command.

1824 **Table 29 – Disable Channel command packet format**

1825 NOTE It is currently unspecified whether this command will cause the Network Controller to cease the pass
 1826 through of traffic from the Management Controller to the network, or if this can only be done using the Disable
 1827 Channel Network TX command.

1828 **8.4.12 Disable Channel response (0x84)**

1829 No command-specific reason code is identified for this response (see Table 30).

1830 **Table 30 – Disable Channel response packet format**

24..45	Pad

1831 **8.4.13 Reset Channel command (0x05)**

1832 The Reset Channel command allows the Management Controller to put the channel into the Initial State.
 1833 Packet transmission is not required to stop until the Reset Channel response has been sent. Thus, the
 1834 Management Controller should be aware that it may receive a number of packets from the channel before
 1835 receiving the response to the Reset Channel command.

1836 Table 31 illustrates the packet format of the Reset Channel command.

1837 **Table 31 – Reset Channel command packet format**

20..23	Checksum			
24..45	Pad			

1841 **8.4.15 Enable Channel Network TX command (0x06)**

1842 The Enable Channel Network TX command shall enable the channel to transmit Pass-through packets
 1843 onto the network. After network transmission is enabled, this setting shall remain enabled until a Disable
 1844 Channel Network TX command is received or the channel enters the Initial State.

1845 The intention of this command is to control which Network Controller ports are allowed to transmit to the
 1846 external network. The Network Controller compares the source MAC address in outgoing Pass-through
 1847 packets to the unicast MAC address(es) configured using the Set MAC Address command. If a match
 1848 exists, the packet is transmitted to the network.

1849 Table 33 illustrates the packet format of the Enable Channel Network TX command.

1850

Table 33 – Enable Channel Network TX command packet format

20..23	Checksum			
24..45	Pad			

1855 **8.4.17 Disable Channel Network TX command (0x07)**

1856 The Disable Channel Network TX command disables the channel from transmitting Pass-through packets
 1857 onto the network. After network transmission is disabled, it shall remain disabled until an Enable Channel
 1858 Network TX command is received.

1859 Table 35 illustrates the packet format of the Disable Channel Network TX command.

1860 **Table 35 – Disable Channel Network TX command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..23	Pad			

1861 **8.4.18 Disable Channel Network TX response (0x87)**

1862 The NC-SI shall, in the absence of a checksum error or identifier mismatch, always accept the Disable
 1863 Channel Network TX command and send a response.

1864 Currently no command-specific reason code is identified for this response (see Table 36).

1865 **Table 36 – Disable Channel Network TX response packet format**

	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

1866 **8.4.19 AEN Enable command (0x08)**

1867 Network Controller implementations shall support this command on the condition that the Network
 1868 Controller generates one or more standard AENs. The AEN Enable command enables and disables the
 1869 different standard AENs supported by the Network Controller. The Network Controller shall copy the AEN

1870 MC ID field from the AEN Enable command into the MC ID field in every subsequent AEN sent to the
 1871 Management Controller.

1872 For more information, see 8.5 ("AEN packet formats") and 8.2.1.1 ("Management Controller ID").

1873 Control of transport-specific AENs is outside the scope of this specification, and should be defined by the
 1874 particular transport binding specifications.

1875 Table 37 illustrates the packet format of the AEN Enable command.

1876 **Table 37 – AEN Enable command packet format**

Bytes		Bits			
Bytes	31..24	23..16	15..08	07..00

20..23	AEN Control				
24..27	Checksum				
28..45	Pad				

1877 The AEN Control field has the format shown in Table 38.

1878 **Table 38 – Format of AEN control**

Bit Position	Field Description	Value Description
0	Link Status Change AEN control	0b = Disable Link Status Change AEN 1b = Enable Link Status Change AEN
1	Configuration Required AEN control	0b = Disable Configuration Required AEN 1b = Enable Configuration Required AEN
2	Host NC Driver Status Change AEN control	0b = Disable Host NC Driver Status Change AEN 1b = Enable Host NC Driver Status Change AEN
15..3	Reserved	Reserved
31..16	OEM-specific AEN control	OEM-specific control

1879 **8.4.20 AEN Enable response (0x88)**

1880 Currently no command-specific reason code is identified for this response (see Table 39).

1881 **Table 39 – AEN Enable response packet format**

		Bits			
Bytes		31..24	23..16	15..08	07..00
00..15	NC-SI Header				
16..19	Response Code		Reason Code		
20..23	Checksum				
24..45	Pad				

1882 **8.4.21 Set Link command (0x09)**

1883 The Set Link command may be used by the Management Controller to configure the external network
 1884 interface associated with the channel by using the provided settings. Upon receiving this command, while
 1885 the host NC driver is not operational, the channel shall attempt to set the link to the configuration
 1886 specified by the parameters. Upon successful completion of this command, link settings specified in the
 1887 command should be used by the network controller as long as the host NC driver does not overwrite the
 1888 link settings.

1889 In the absence of an operational host NC driver, the NC should attempt to make the requested link state
 1890 change even if it requires the NC to drop the current link. The channel shall send a response packet to
 1891 the Management Controller within the required response time. However, this specification does not
 1892 specify the amount of time the requested link state changes take to complete
 1893 The actual link settings are controlled by the host NC driver when it is operational. When the host NC
 1894 driver is operational, link settings specified by the MC using the Set Link command may be overwritten by
 1895 the host NC driver. The link settings are not restored by the NC if the host NC driver becomes non-
 1896 operational.

1897 Table 40 illustrates the packet format of the Set Link command.

1898 **Table 40 – Set Link command packet format**

		Bits			
Bytes		31..24	23..16	15..08	07..00

16..19	Link Settings				
20..23	OEM Link Settings				
24..27	Checksum				
28..45	Pad				

1899 Table 41 and Table 42 describe the Set Link bit definitions. Refer to [IEEE 802.3](#) for definitions of Auto
1900 Negotiation, Duplex Setting, Pause Capability, and Asymmetric Pause Capability.

1901

Table 41 – Set Link bit definitions

Bit Position	Field Description	Value Description
00	Auto Negotiation	1b = enable 0b = disable
01..07	Link Speed Selection More than one speed can be selected when Auto Negotiation is set to 'enable'. If Auto Negotiation is not used, the channel attempts to force the link to the specified setting (in this case, if the setting is not supported or if multiple speeds are enabled, a Command Failed response code and Parameter Is Invalid, Unsupported, or Out-of-Range reason code shall be returned). NOTE Additional link speeds are defined below.	Bit 01: 1b = enable 10 Mbps
		Bit 02: 1b = enable 100 Mbps
		Bit 03: 1b = enable 1000 Mbps (1 Gbps)
		Bit 04: 1b = enable 10 Gbps
		Bit 05: 1b = enable 20 Gbps (optional for NC-SI 1.1, RESERVED for NC-SI 1.0)
		Bit 06: 1b = enable 25 Gbps (optional for NC-SI 1.1, RESERVED for NC-SI 1.0)
		Bit 07: 1b = enable 40 Gbps (optional for NC-SI 1.1, RESERVED for NC-SI 1.0)
08..09	Duplex Setting (separate duplex setting bits) More than one duplex setting can be selected when Auto Negotiation is set to 'enable'. If Auto Negotiation is not used, the channel attempts to force the link to the specified setting (in this case, if the setting is not supported or if multiple settings are enabled, a Command Failed response code and Parameter Is Invalid, Unsupported, or Out-of-Range reason code shall be returned).	Bit 08: 1b = enable half-duplex
		Bit 09: 1b = enable full-duplex
10	Pause Capability If Auto Negotiation is not used, the channel should apply pause settings assuming the partner supports the same capability.	1b = disable 0b = enable
11	Asymmetric Pause Capability If Auto Negotiation is not used, the channel should apply asymmetric pause settings assuming the partner supports the same capability.	1b = enable 0b = disable
12	OEM Link Settings Field Valid (see Table 42)	1b = enable 0b = disable
13..16	Additional Link Speeds (see Link Speed Selection)	Bit 13: 1b = enable 50 Gbps (optional for NC-SI 1.1, RESERVED for NC-SI 1.0) Bit 14: 1b = enable 100 Gbps (optional for NC-SI 1.1, RESERVED for NC-SI 1.0) Bit 15: 1b = enable 2.5 Gbps (optional for NC-SI 1.1, RESERVED for NC-SI 1.0) Bit 16: 1b = enable 5 Gbps (optional for NC-SI 1.1, RESERVED for NC-SI 1.0)
17..31	Reserved	0

1902

Table 42 – OEM Set Link bit definitions

Bit Position	Field Description	Value Description
00..31	OEM Link Settings	Vendor specified

1903

8.4.22 Set Link Response (0x89)

1904 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Set Link
 1905 command and send a response (see Table 43). In the presence of an operational Host NC driver, the NC
 1906 should not attempt to make link state changes and should send a response with reason code 0x1 (Set
 1907 Link Host OS/ Driver Conflict).

1908 If the Auto Negotiation field is set, the NC should ignore Link Speed Selection and Duplex Setting fields
 1909 that are not supported by the NC.

1910

Table 43 – Set Link response packet format

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

1911 Table 44 describes the reason codes that are specific to the Set Link command. Returning the following
 1912 command-specific codes is recommended, conditional upon Network Controller support for the related
 1913 capabilities.

1914

Table 44 – Set Link command-specific reason codes

Value	Description	Comment
0x0901	Set Link Host OS/ Driver Conflict	Returned when the Set Link command is received when the Host NC driver is operational
0x0902	Set Link Media Conflict	Returned when Set Link command parameters conflict with the media type (for example, Fiber Media)
0x0903	Set Link Parameter Conflict	Returned when Set Link parameters conflict with each other (for example, 1000 Mbps HD with copper media)
0x0904	Set Link Power Mode Conflict	Returned when Set Link parameters conflict with current low-power levels by exceeding capability
0x0905	Set Link Speed Conflict	Returned when Set Link parameters attempt to force more than one speed at the same time
0x0906	Link Command Failed-Hardware Access Error	Returned when PHY R/W access fails to complete normally while executing the Set Link or Get Link Status command

1915 **8.4.23 Get Link Status command (0x0A)**

1916 The Get Link Status command allows the Management Controller to query the channel for potential link
 1917 status and error conditions (see Table 45).

1918 **Table 45 – Get Link Status command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

1919 **8.4.24 Get Link Status response (0x8A)**

1920 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get Link
 1921 Status command and send a response (see Table 46).

1922 **Table 46 – Get Link Status response packet format**

1929 Table 50 describes the reason code that is specific to the Get Link Status command.

1930 **Table 50 – Get Link Status command-specific reason code**

Value	Description	Comment
0x0A06	Link Command Failed-Hardware Access Error	Returned when PHY R/W access fails to complete normally while executing the Set Link or Get Link Status command

1931 8.4.25 Set VLAN Filter command (0x0B)

1932 The Set VLAN Filter command is used by the Management Controller to program one or more VLAN IDs
1933 that are used for VLAN filtering.

1934 Incoming packets that match both a VLAN ID filter and a MAC address filter are forwarded to the
1935 Management Controller. Other packets may be dropped based on the VLAN filtering mode per the Enable
1936 VLAN command.

1937 The quantity of each filter type that is supported by the channel can be discovered by means of the Get
1938 Capabilities command. Up to 15 filters can be supported per channel. A Network Controller
1939 implementation shall support at least one VLAN filter per channel.

1940 To configure a VLAN filter, the Management Controller issues a Set VLAN Filter command with the Filter
1941 Selector field indicating which filter is to be configured, the VLAN ID field set to the VLAN TAG values to
1942 be used by the filter, and the Enable field set to either enable or disable the selected filter.

1943 The VLAN-related fields are specified per [IEEE 802.1q](#). When VLAN Tagging is used, the packet includes
1944 a Tag Protocol Identifier (TPID) field and VLAN Tag fields, as shown in Table 51.

1945 **Table 51 – IEEE 802.1q VLAN Fields**

Field	Size	Description
TPID	2 bytes	Tag Protocol Identifier = 8100h
VLAN TAG – user priority	3 bits	User Priority (typical value = 000b)
VLAN TAG – CFI	1 bit	Canonical Format Indicator = 0b
VLAN TAG – VLAN ID	12 bits	Zeros = no VLAN

1946 When checking VLAN field values, the Network Controller shall match against the enabled VLAN Tag
1947 Filter values that were configured with the Set VLAN Filter command. The Network Controller shall also
1948 match on the TPID value of 8100h, as specified by [IEEE 802.1q](#). Matching against the User Priority/CFI
1949 bits is optional. An implementation may elect to ignore the setting of those fields.

1950 Table 52 illustrates the packet format of the Set VLAN Filter command.

1951 **Table 52 – Set VLAN Filter command packet format**

		Bits

1966 Table 58 describes the modes for the Enable VLAN command.

1967 **Table 58 – VLAN Enable modes**

Mode	#	O/M	Description
Reserved	0x00	N/A	Reserved
VLAN only	0x01	M	Only VLAN-tagged packets that match the enabled VLAN Filter settings (and also match the MAC Address Filtering configuration) are accepted. Non-VLAN-tagged packets are not accepted.
VLAN + non-VLAN	0x02	O	VLAN-tagged packets that match the enabled VLAN Filter settings (and also match the MAC Address Filtering configuration) are accepted. Non-VLAN-tagged packets (that also match the MAC Address Filtering configuration) are also accepted.
Any VLAN + non-VLAN	0x03	O	Any VLAN-tagged packets that also match the MAC Address Filtering configuration are accepted, regardless of the VLAN Filter settings. Non-VLAN-tagged packets (that also match the MAC Address Filtering configuration) are also accepted.
Reserved	0x04 – 0xFF	N/A	Reserved

1968 **8.4.28 Enable VLAN response (0x8C)**

1969 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Enable
 1970 VLAN command and send a response.

1971 Currently no command-specific reason code is identified for this response (see Table 59).

1972 **Table 59 – Enable VLAN response packet format**

	Bits

24..45	Pad			

1973 **8.4.29 Disable VLAN command (0x0D)**

1974 The Disable VLAN command may be used by the Management Controller to disable VLAN filtering. In the
 1975 disabled state, only non-VLAN-tagged packets (that also match the MAC Address Filtering configuration)
 1976 are accepted. VLAN-tagged packets are not accepted.

1977 Table 60 illustrates the packet format of the Disable VLAN command.

16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

1984 **8.4.31 Set MAC Address command (0x0E)**

1985 The Set MAC Address command is used by the Management Controller to program the channel's unicast
1986 or multicast MAC address filters.

1987 The channel supports one or more “perfect match” MAC address filters that are used to selectively
1988 forward inbound frames to the Management Controller. Assuming that a packet passes any VLAN filtering
1989 that may be active, it will be forwarded to the Management Controller if its 48-bit destination MAC address
1990 exactly matches an active MAC address filter.

1991 MAC address filters may be configured as unicast or multicast addresses, depending on the capability of
1992 the channel. The channel may implement three distinct types of filter:

- 1993 • **Unicast filters** support exact matching on 48-bit unicast MAC addresses (AT = 0x0 only).
- 1994 • **Multicast filters** support exact matching on 48-bit multicast MAC addresses (AT = 0x1 only).
- 1995 • **Mixed filters** support matching on both unicast and multicast MAC addresses. (AT=0x0 or
1996 AT=0x1)

1997 The number of each type of filter that is supported by the channel can be discovered by means of the Get
1998 Capabilities command. The channel shall support at least one unicast address filter or one mixed filter, so
1999 that at least one unicast MAC address filter may be configured on the channel. Support for any
2000 combination of unicast, multicast, or mixed filters beyond this basic requirement is vendor specific. The
2001 total number of all filters shall be less than or equal to 8.

2002 To configure an address filter, the Management Controller issues a Set MAC Address command with the
2003 Address Type field indicating the type of address to be programmed (unicast or multicast) and the MAC
2004 Address Num field indicating the specific filter to be programmed.

2005 Filters are addressed using a 1-based index ordered over the unicast, multicast, and mixed filters
2006 reported by means of the Get Capabilities command. For example, if the interface reports four unicast
2007 filters, two multicast filters, and two mixed filters, then MAC Address numbers 1 through 4 refer to the
2008 interface's unicast filters, 5 and 6 refer to the multicast filters, and 7 and 8 refer to the mixed filters.
2009 Similarly, if the interface reports two unicast filters, no multicast filters, and six mixed filters, then MAC
2010 address numbers 1 and 2 refer to the unicast filters, and 3 through 8 refer to the mixed filters.

- 2011 The filter type of the filter to be programmed (unicast, multicast, or mixed) shall be compatible with the
- 2012 Address Type being programmed. For example, programming a mixed filter to a unicast address is
- 2013 allowed, but programming a multicast filter to a unicast address is an error.

- 2014 The Enable field determines whether the indicated filter is to be enabled or disabled. When a filter is
- 2015 programmed to be enabled, the filter is loaded with the 48-bit MAC address in the MAC Address field of
- 2016 the command, and the channel enables forwarding of frames that match the configured address. If the
- 2017 specified filter was already enabled, it is updated with the new address provided.

- 2018 When a filter is programmed to be disabled, the contents of the MAC Address field are ignored. Any
- 2019 previous MAC address programmed in the filter is discarded and the channel no longer uses this filter in
- 2020 its packet-forwarding function.

- 2021 Only unicast MAC addresses, specified with AT set to 0x0, should be used in source MAC address
- 2022 checking and for determining the NC-SI channel for Pass-through transmit traffic.

- 2023 Table 62 illustrates the packet format of the Set MAC Address command.

2024 **Table 62 – Set MAC Address command packet format**

2035 **Table 67 – Set MAC Address command-specific reason code**

Value	Description	Comment
0x0E08	MAC Address Is Zero	Returned when the Set MAC Address command is received with the MAC address set to 0

2036 **8.4.33 Enable Broadcast Filter command (0x10)**

2037 The Enable Broadcast Filter command allows the Management Controller to control the forwarding of
2038 broadcast frames to the Management Controller. The channel, upon receiving and processing this
2039 command, shall filter all received broadcast frames based on the broadcast packet filtering settings
2040 specified in the payload. If no broadcast packet types are specified for forwarding, all broadcast packets
2041 shall be filtered out.

2042 The Broadcast Packet Filter Settings field is used to specify those protocol-specific broadcast filters that
2043 should be activated. The channel indicates which broadcast filters it supports in the Broadcast Filter
2044 Capabilities field of the Get Capabilities Response frame defined in 8.4.46.

2045 Table 68 illustrates the packet format of the Enable Broadcast Filter command.

2046

2048

Table 69 – Broadcast Packet Filter Settings field

Bit Position	Field Description	Value Description
0	ARP Packets	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an ARP broadcast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> • The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF). • The EtherType field set to 0x0806. <p>This field is mandatory.</p>
1	DHCP Client Packets	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, a DHCP client broadcast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> • The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF). • The EtherType field is set to 0x0800 (IPv4). • The IP header's Protocol field is set to 17 (UDP). • The UDP destination port number is set to 68. <p>This field is optional. If unsupported, broadcast DHCP client packets will be blocked when broadcast filtering is enabled. The value shall be set to 0 if unsupported.</p>

Bit Position	Field Description	Value Description
2	DHCP Server Packets	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, a DHCP server broadcast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF). The EtherType field is set to 0x0800 (IPv4). The IP header's Protocol field is set to 17 (UDP). The UDP destination port number is set to 67. <p>This field is optional. If unsupported, broadcast DHCP packets will be blocked when broadcast filtering is enabled. The value shall be set to 0 if unsupported.</p>
3	NetBIOS Packets	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, NetBIOS broadcast packets are defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF). The EtherType field is set to 0x0800 (IPv4). The IP header's Protocol field is set to 17 (UDP). The UDP destination port number is set to 137 for NetBIOS Name Service or 138 for NetBIOS Datagram Service, per the assignment of IANA well-known ports. <p>This field is optional. If unsupported, broadcast NetBIOS packets will be blocked when broadcast filtering is enabled. The value shall be set to 0 if unsupported.</p>
4..31	Reserved	None

2049 **8.4.34 Enable Broadcast Filter response (0x90)**

2050 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Enable
2051 Broadcast Filter command and send a response.

2052 Currently no command-specific reason code is identified for this response (see Table 70).

2053 **Table 70 – Enable Broadcast Filter response packet format**

24..45	Pad			

2054 **8.4.35 Disable Broadcast Filter command (0x11)**

2055 The Disable Broadcast Filter command may be used by the Management Controller to disable the
 2056 broadcast filter feature and enable the reception of all broadcast frames. Upon processing this command,
 2057 the channel shall discontinue the filtering of received broadcast frames.

2058 Table 71 illustrates the packet format of the Disable Broadcast Filter command.

2059 **Table 71 – Disable Broadcast Filter command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

2060 **8.4.36 Disable Broadcast Filter response (0x91)**

2061 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Disable
 2062 Broadcast Filter command and send a response.

2063 Currently no command-specific reason code is identified for this response (see Table 72).

2064 **Table 72 – Disable Broadcast Filter response packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00

16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

2065 **8.4.37 Enable Global Multicast Filter command (0x12)**

2066 The Enable Global Multicast Filter command is used to activate global filtering of multicast frames with
 2067 optional filtering of specific multicast protocols. Upon receiving and processing this command, the
 2068 channel shall only deliver multicast frames that match specific multicast MAC addresses enabled for Pass
 2069 through using this command or the Set MAC Address command.

2070 The Multicast Packet Filter Settings field is used to specify optional, protocol-specific multicast filters that
 2071 should be activated. The channel indicates which optional multicast filters it supports in the Multicast Filter
 2072 Capabilities field of the Get Capabilities Response frame defined in 8.4.46. The Management Controller
 2073 should not set bits in the Multicast Packet Filter Settings field that are not indicated as supported in the
 2074 Multicast Filter Capabilities field.

2075 Neighbor Solicitation messages are sent to a Solicited Node multicast address that is derived from the
 2076 target node's IPv6 address. This command may be used to enable forwarding of solicited node
 2077 multicasts.

2078 The IPv6 neighbor solicitation filter, as defined in this command, may not be supported by the Network
 2079 Controller. In this case, the Management Controller may configure a multicast or mixed MAC address
 2080 filter for the specific Solicited Node multicast address using the Set MAC Address command to enable
 2081 forwarding of Solicited Node multicasts.

2082 This command shall be implemented if the channel implementation supports accepting all multicast
 2083 addresses. An implementation that does not support accepting all multicast addresses shall not
 2084 implement these commands. Pass-through packets with multicast addresses can still be accepted
 2085 depending on multicast address filter support provided by the Set MAC Address command. Multicast filter
 2086 entries that are set to be enabled in the Set MAC Address command are accepted; all others are rejected.
 2087 Table 73 illustrates the packet format of the Enable Global Multicast Filter command. Unsupported fields
 2088 should be treated as reserved fields unless otherwise specified.

2089

2090 **Table 73 – Enable Global Multicast Filter command packet format**

Bytes		Bits			
Bytes	31..24	23..16	15..08	07..00	
00..15	NC-SI Header				
16..19	Multicast Packet Filter Settings				
20..23	Checksum				
24..45	Pad				

2091 Table 74 describes the bit definitions for the Multicast Packet Filter Settings field.

2092 **Table 74 – Bit Definitions for Multicast Packet Filter Settings field**

Bit Position	Field Description	Value Description
0	IPv6 Neighbor Advertisement	1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type. For the purposes of this specification, an IPv6 Neighbor Advertisement multicast packet is defined to be any packet that meets all of the following requirements: <ul style="list-style-type: none"> • The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This address corresponds to the All_Nodes (FF02::1) multicast address. • The EtherType field is set to 0x86DD (IPv6). • The IPv6 header's Next Header field is set to 58 (ICMPv6). • The ICMPv6 header's Message Type field is set to the following value: 136 – Neighbor Advertisement. This field is optional.

Bit Position	Field Description	Value Description
1	IPv6 Router Advertisement	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an IPv6 Router Advertisement multicast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> • The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This corresponds to the All_Nodes multicast address, FF02::1. • The EtherType field is set to 0x86DD (IPv6). • The IPv6 header's Next Header field is set to 58 (ICMPv6). • The ICMPv6 header's Message Type field is set to 134. <p>This field is optional.</p>
2	DHCPv6 relay and server multicast	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, a DHCPv6 multicast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> • The destination MAC address field is set to the layer 2 multicast address 33:33:00:01:00:02 or 33:33:00:01:00:03. These correspond to the IPv6 multicast addresses FF02::1:2 (All_DHCP_Relay_Agents_and_Servers) and FF05::1:3 (All_DHCP_Servers). • The EtherType field is set to 0x86DD (IPv6). • The IPv6 header's Next Header field is set to 17 (UDP). • The UDP destination port number is set to 547. <p>This field is optional.</p>
3	DHCPv6 multicasts from server to clients listening on well-known UDP ports	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, a DHCPv6 multicast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> • The destination MAC address field is set to the layer 2 multicast address 33:33:00:01:00:02. These correspond to the IPv6 multicast addresses FF02::1:2 (All_DHCP_Relay_Agents_and_Servers). • The EtherType field is set to 0x86DD (IPv6). • The IPv6 header's Next Header field is set to 17 (UDP). • The UDP destination port number is set to 546. <p>This field is optional.</p>

Bit Position	Field Description	Value Description
4	IPv6 MLD	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an IPv6 MLD packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This address corresponds to the All_Nodes (FF02::1) multicast address. The EtherType field is set to 0x86DD (IPv6). The IPv6 header's Next Header field is set to 58 (ICMPv6). The ICMPv6 header's Message Type field is set to one of the following values: 130 (Multicast Listener Query), 131 (Multicast Listener Report), 132 (Multicast Listener Done) <p>This field is optional.</p>
5	IPv6 Neighbor Solicitation	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an IPv6 MLD packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> The destination MAC address field is set to a layer 2 multicast address of the form 33:33:FF:XX:XX:XX. This address corresponds to the Solicited Node multicast address where the last three bytes of the destination MAC address are ignored for this filter. The EtherType field is set to 0x86DD (IPv6). The IPv6 header's Next Header field is set to 58 (ICMPv6). The ICMPv6 header's Message Type field is set to one of the following values: 135 <p>This field is optional.</p> <p>IMPLEMENTATION NOTE Enabling of this filter results in receiving all IPv6 neighbor solicitation traffic on this channel. If IPv6 neighbor solicitation traffic for a specific multicast address is of interest, then it is recommended that the MC uses a multicast address filter (configured for the multicast address using the Set MAC Address command) instead of this filter.</p>
31..6	Reserved	None

2093 **8.4.38 Enable Global Multicast Filter response (0x92)**

2094 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Enable
2095 Global Multicast Filter command and send a response.

2096 Currently no command-specific reason code is identified for this response (see Table 75).

2097

Table 75 – Enable Global Multicast Filter response packet format

		Bits			
Bytes		31..24	23..16	15..08	07..00
00..15		NC-SI Header			
16..19		Response Code		Reason Code	
20..23		Checksum			
24..45		Pad			

2098 **8.4.39 Disable Global Multicast Filter command (0x13)**

2099 The Disable Global Multicast Filter command is used to disable global filtering of multicast frames. Upon
 2100 receiving and processing this command, and regardless of the current state of multicast filtering, the
 2101 channel shall forward all multicast frames to the Management Controller.

2102 This command shall be implemented on the condition that the channel implementation supports accepting
 2103 all multicast addresses. An implementation that does not support accepting all multicast addresses shall
 2104 not implement these commands. Pass-through packets with multicast addresses can still be accepted
 2105 depending on multicast address filter support provided by the Set MAC Address command. Packets with
 2106 destination addresses matching multicast filter entries that are set to enabled in the Set MAC Address
 2107 command are accepted; all others are rejected.

2108 Table 76 illustrates the packet format of the Disable Global Multicast Filter command.

2109

Table 76 – Disable Global Multicast Filter command packet format

Bytes		31..24	23..16	15..08	07..00
00..15		NC-SI Header			
16..19		Checksum			
20..45		Pad			

2110 **8.4.40 Disable Global Multicast Filter response (0x93)**

2111 In the absence of any errors, the channel shall process and respond to the Disable Global Multicast Filter
 2112 command by sending the response packet shown in Table 77.

2113 Currently no command-specific reason code is identified for this response.

2114

Table 77 – Disable Global Multicast Filter response packet format

		Bits			
Bytes		31..24	23..16	15..08	07..00
00..15		NC-SI Header			
16..19		Response Code		Reason Code	
20..23		Checksum			
24..45		Pad			

2115 **8.4.41 Set NC-SI Flow Control command (0x14)**

2116 The Set NC-SI Flow Control command allows the Management Controller to configure [IEEE 802.3](#) pause
 2117 packet flow control on the NC-SI.

2118 The Set NC-SI Flow Control command is addressed to the package, rather than to a particular channel
 2119 (that is, the command is sent with a Channel ID where the Package ID subfield matches the ID of the
 2120 intended package and the Internal Channel ID subfield is set to 0x1F).

2121 When enabled for flow control, a channel may direct the package to generate and renew 802.3x (XOFF)
 2122 PAUSE Frames for a maximum interval of T12 for a single congestion condition. If the congestion
 2123 condition remains in place after a second T12 interval expires, the congested channel shall enter the
 2124 Initial State and remove its XOFF request to the package. Note that some implementations may have
 2125 shared buffering arrangements where all channels within the package become congested simultaneously.
 2126 Also note that if channels become congested independently, the package may not immediately go into
 2127 the XON state after T12 if other channels within the package are still requesting XOFF.

2128 The setting of [IEEE 802.3](#) pause packet flow control on the NC-SI is independent from any arbitration
 2129 scheme, if any is used.

2130 Table 78 illustrates the packet format of the Set NC-SI Flow Control command.

2131 **Table 78 – Set NC-SI Flow Control command packet format**

		Bits			
Bytes		31..24	23..16	15..08	07..00

20..23	NC-SI Version			
	Major	Minor	Update	Alpha1
24..27	reserved	reserved	reserved	Alpha2
28..31	Firmware Name String (11-08)			
32..35	Firmware Name String (07-04)			
36..39	Firmware Name String (03-00)			
40..43	Firmware Version			
	MS-byte (3)	Byte (2)	Byte (1)	LS-byte (0)
44..47	PCI DID		PCI VID	
48..51	PCI SSID		PCI SVID	
52..55	Manufacturer ID (IANA)			
56..59	Checksum			

2150 **8.4.44.1 NC-SI Version encoding**

2151 The NC-SI Version field holds the version number of the NC-SI specification with which the controller is
2152 compatible. The version field shall be encoded as follows:

- 2153 • The 'major', 'minor', and 'update' bytes are BCD-encoded, and each byte holds two BCD digits.
- 2154 • The 'alpha' byte holds an optional alphanumeric character extension that is encoded using the
2155 ISO/IEC 8859-1 Character Set.
- 2156 • The semantics of these fields follow the semantics specified in [DSP4014](#).
- 2157 • The value 0x00 in the Alpha1 or Alpha2 fields means that the corresponding alpha field is not
2158 used. The Alpha1 field shall be used first.
- 2159 • The value 0xF in the most-significant nibble of a BCD-encoded value indicates that the most-
2160 significant nibble should be ignored and the overall field treated as a single digit value.
- 2161 • A value of 0xFF in the update field indicates that the entire field is not present. 0xFF is not
2162 allowed as a value for the major or minor fields.

2163 EXAMPLE: Version 3.7.10a → 0xF3F7104100
 2164 Version 10.01.7 → 0x1001F70000
 2165 Version 3.1 → 0xF3F1FF0000
 2166 Version 1.0a → 0xF1F0FF4100
 2167 Version 1.0ab → 0xF1F0FF4142 (Alpha1 = 0x41, Alpha2 = 0x42)

2168 8.4.44.2 Firmware Name encoding

2169 The Firmware Name String shall be encoded using the ISO/IEC 8859-1 Character Set. Strings are left-
2170 justified where the leftmost character of the string occupies the most-significant byte position of the
2171 Firmware Name String field, and characters are populated starting from that byte position. The string is
2172 null terminated if the string is smaller than the field size. That is, the delimiter value, 0x00, follows the last
2173 character of the string if the string occupies fewer bytes than the size of the field allows. A delimiter is not
2174 required if the string occupies the full size of the field. Bytes following the delimiter (if any) should be
2175 ignored and can be any value.

2176 8.4.44.3 Firmware Version encoding

2177 To facilitate a common way of representing and displaying firmware version numbers across different
2178 vendors, each byte is hexadecimal encoded where each byte in the field holds two hexadecimal digits.
2179 The Firmware Version field shall be encoded as follows. The bytes are collected into a single 32-bit field
2180 where each byte represents a different 'point number' of the overall version. The selection of values that
2181 represent a particular version of firmware is specific to the Network Controller vendor.

2182 Software displaying these numbers should not suppress leading zeros, which should help avoid user
2183 confusion in interpreting the numbers. For example, consider the two values 0x05 and 0x31.
2184 Numerically, the byte 0x31 is greater than 0x05, but if leading zeros were incorrectly suppressed, the two
2185 displayed values would be ".5" and ".31", respectively, and a user would generally interpret 0.5 as
2186 representing a greater value than 0.31 instead of 0.05 being smaller than 0.31. Similarly, if leading zeros
2187 were incorrectly suppressed, the value 0x01 and 0x10 would be displayed as 0.1 and 0.10, which could
2188 potentially be misinterpreted as representing the same version instead of 0.01 and 0.10 versions.

2189 EXAMPLE: 0x00030217 → Version 00.03.02.17
2190 0x010100A0 → Version 01.01.00.A0

2191 8.4.44.4 PCI ID fields

2192 These fields (PCI DID, PCI VID, PCI SSID, PCI SVID) hold the PCI ID information for the Network
2193 Controller when the Network Controller incorporates a PCI or PCI Express™ interface that provides a
2194 host network interface connection that is shared with the NC-SI connection to the network.

2195 If this field is not used, the values shall all be set to zeros (0000h). Otherwise, the fields shall hold the
2196 PCI ID information for the host interface as defined by the version of the PCI/PCI Express™ specification
2197 to which the device's interface was designed.

2198 8.4.44.5 Manufacturer ID (IANA) field

2199 The Manufacturer ID holds the [IANA Enterprise Number](#) for the manufacturer of the Network Controller as
2200 a 32-bit binary number. If the field is unused, the value shall be set to 0xFFFFFFFF.

2201 **8.4.45 Get Capabilities command (0x16)**

2202 The Get Capabilities command is used to discover additional optional functions supported by the channel,
 2203 such as the number of unicast/multicast addresses supported, the amount of buffering in bytes available
 2204 for packets bound for the Management Controller, and so on.

2205 Table 84 illustrates the packet format for the Get Capabilities command.

2206 **Table 84 – Get Capabilities command packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

2207 **8.4.46 Get Capabilities response (0x96)**

2208 In the absence of any errors, the channel shall process and respond to the Get Capabilities Command
 2209 and send the response packet shown in Table 85. Currently no command-specific reason code is
 2210 identified for this response.

2211 **Table 85 – Get Capabilities response packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Capabilities Flags			
24..27	Broadcast Packet Filter Capabilities			
28..31	Multicast Packet Filter Capabilities			
32..35	Buffering Capability			
36..39	AEN Control Support			
40..43	VLAN Filter Count	Mixed Filter Count	Multicast Filter Count	Unicast Filter Count
44..47	Reserved		VLAN Mode Support	Channel Count
48..51	Checksum			

2212 **8.4.46.1 Capabilities Flags field**

2213 The Capabilities Flags field indicates which optional features of this specification the channel supports, as
 2214 described in Table 86.

2215

Table 86 – Capabilities Flags bit definitions

Bit Position	Field Description	Value Description
0	Hardware Arbitration Capability	0b = Hardware arbitration capability is not supported by the package. 1b = Hardware arbitration capability is supported by the package.
1	Host NC Driver Status	0b = Host NC Driver Indication status is not supported. 1b = Host NC Driver Indication status is supported. See Table 48 for the definition of Host NC Driver Indication Status.
2	Network Controller to Management Controller Flow Control Support	0b = Network Controller to Management Controller flow control is not supported. 1b = Network Controller to Management Controller flow control is supported.
3	Management Controller to Network Controller Flow Control Support	0b = Management Controller to Network Controller flow control is not supported. 1b = Management Controller to Network Controller flow control is supported.
4	All multicast addresses support	0b = The channel cannot accept all multicast addresses. The channel does not support enable/disable global multicast commands. 1b = The channel can accept all multicast addresses. The channel supports enable/disable global multicast commands.
6..5	Hardware Arbitration Implementation Status	00b = Unknown 01b = Hardware arbitration capability is not implemented for the package on the given system. 10b = Hardware arbitration capability is implemented for the package on the given system. 11b = Reserved.
7..31	Reserved	Reserved

2216 8.4.46.2 Broadcast Packet Filter Capabilities field

2217 The Broadcast Packet Filter Capabilities field defines the optional broadcast packet filtering capabilities
2218 that the channel supports. The bit definitions for this field correspond directly with the bit definitions for the
2219 Broadcast Packet Filter Settings field defined for the Enable Broadcast Filter command in Table 69. A bit
2220 set to 1 indicates that the channel supports the filter associated with that bit position; otherwise, the
2221 channel does not support that filter.

2222 8.4.46.3 Multicast Packet Filter Capabilities field

2223 The Multicast Packet Filter Capabilities field defines the optional multicast packet filtering capabilities that
2224 the channel supports. The bit definitions for this field correspond directly with the bit definitions for the
2225 Multicast Packet Filter Settings field defined for the Enable Global Multicast Filter command in Table 74.
2226 A bit set to 1 indicates that the channel supports the filter associated with that bit position; otherwise, the
2227 channel does not support that filter.

2228 **8.4.46.4 Buffering Capability field**

2229 The Buffering Capability field defines the amount of buffering in bytes that the channel provides for
 2230 inbound packets destined for the Management Controller. The Management Controller may make use of
 2231 this value in software-based Device Selection implementations to determine the relative time for which a
 2232 specific channel may be disabled before it is likely to start dropping packets. A value of 0 indicates that
 2233 the amount of buffering is unspecified.

2234 **8.4.46.5 AEN Control Support field**

2235 The AEN Control Support field indicates various standard AENs supported by the implementation. The
 2236 format of the field is shown in Table 38.

2237 **8.4.46.6 VLAN Filter Count field**

2238 The VLAN Filter Count field indicates the number of VLAN filters, up to 15, that the channel supports, as
 2239 defined by the Set VLAN Filter command.

2240 **8.4.46.7 Mixed, Multicast, and Unicast Filter Count fields**

2241 The Mixed Filter Count field indicates the number of mixed address filters that the channel supports. A
 2242 mixed address filter can be used to filter on specific unicast or multicast MAC addresses.

2243 The Multicast Filter Count field indicates the number of multicast MAC address filters that the channel
 2244 supports.

2245 The Unicast Filter Count field indicates the number of unicast MAC address filters that the channel
 2246 supports.

2247 The channel is required to support at least one unicast or mixed filter, such that at least one unicast MAC
 2248 address can be configured on the interface. The total number of unicast, multicast, and mixed filters shall
 2249 not exceed 8.

2250 **8.4.46.8 VLAN Mode Support field**

2251 The VLAN Mode Support field indicates various modes supported by the implementation. The format of
 2252 field is defined in Table 87.

2253

Table 87 – VLAN Mode Support bit definitions

Bit Position	Field Description	Value Description
0	VLAN only	1 = VLAN shall be supported in the implementation.
1	VLAN + non-VLAN	0 = Filtering 'VLAN + non-VLAN' traffic is not supported in the implementation. 1 = Filtering 'VLAN + non-VLAN' traffic is supported in the implementation.
2	Any VLAN + non-VLAN	0 = Filtering 'Any VLAN + non-VLAN' traffic is not supported in the implementation. 1 = Filtering 'Any VLAN + non-VLAN' traffic is supported in the implementation.
3..7	Reserved	0

2254 **8.4.46.9 Channel Count field**

2255 The Channel Count field indicates the number of channels supported by the Network Controller.

2256 **8.4.47 Get Parameters command (0x17)**

2257 The Get Parameters command can be used by the Management Controller to request that the channel
 2258 send the Management Controller a copy of all of the currently stored parameter settings that have been
 2259 put into effect by the Management Controller, plus “other” Host/Channel parameter values that may be
 2260 added to the Get Parameters Response Payload.

2261 Table 88 illustrates the packet format for the Get Parameters command.

2262 **Table 88 – Get Parameters command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

2263 **8.4.48 Get Parameters response (0x97)**

2264 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get
 2265 Parameters command and send a response. As shown in Table 89, each parameter shall return the value
 2266 that was set by the Management Controller. If the parameter is not supported, 0 is returned. Currently no
 2267 command-specific reason code is identified for this response.

2268 The payload length of this response packet will vary according to how many MAC address filters or VLAN
 2269 filters the channel supports. All supported MAC addresses are returned at the end of the packet, without
 2270 any intervening padding between MAC addresses.

2271 MAC addresses are returned in the following order: unicast filtered addresses first, followed by multicast
 2272 filtered addresses, followed by mixed filtered addresses, with the number of each corresponding to those
 2273 reported through the Get Capabilities command. For example, if the interface reports four unicast filters,
 2274 two multicast filters, and two mixed filters, then MAC addresses 1 through 4 are those currently
 2275 configured through the interface’s unicast filters, MAC addresses 5 and 6 are those configured through
 2276 the multicast filters, and 7 and 8 are those configured through the mixed filters. Similarly, if the interface
 2277 reports two unicast filters, no multicast filters, and six mixed filters, then MAC addresses 1 and 2 are
 2278 those currently configured through the unicast filters, and 3 through 8 are those configured through the
 2279 mixed filters.

2280

2281 Table 90 lists the parameters for which values are returned in this response packet. The contents of the
 2282 various configuration value fields, such as MAC Address, VLAN Tags, Link Settings, and Broadcast
 2283 Packet Filter Settings, shall be considered valid only when the corresponding configuration bit is set
 2284 (Enabled) in the Configuration Flags field.

2285

Table 90 – Get Parameters data definition

Parameter Field Name	Description
MAC Address Count	The number of MAC addresses supported by the channel
MAC Address Flags	The enable/disable state for each supported MAC address See Table 91.
VLAN Tag Count	The number of VLAN Tags supported by the channel
VLAN Tag Flags	The enable/disable state for each supported VLAN Tag See Table 92.

Parameter Field Name	Description
Link Settings	The 32-bit Link Settings value as defined in the Set Link command
Broadcast Packet Filter Settings	The current 32-bit Broadcast Packet Filter Settings value
Configuration Flags	See Table 93.
VLAN Mode	See Table 58.
Flow Control Enable	See Table 79.
AEN Control	See Table 38.
MAC Address 1..8	The current contents of up to eight 6-byte MAC address filter values.
VLAN Tag 1..15	The current contents of up to 15 16-bit VLAN Tag filter values
.	.

2286 The format of the MAC Address Flags field is defined in Table 91.

2287 **Table 91 – MAC Address Flags bit definitions**

Bit Position	Field Description	Value Description
0	MAC address 1 status	0b = Default or unsupported or disabled 1b = Enabled
1	MAC address 2 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled
2	MAC address 3 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled
...
7	MAC address 8 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled

2288 The format of the VLAN Tag Flags field is defined in Table 92.

2289 **Table 92 – VLAN Tag Flags bit definitions**

Bit Position	Field Description	Value Description
0	VLAN Tag 1 status	0b = Default or unsupported or disabled 1b = Enabled
1	VLAN Tag 2 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled
2	VLAN Tag 3 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled
...
14	VLAN Tag 15 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled

2290 The format of the Configuration Flags field is defined in Table 93.

2291

Table 93 – Configuration Flags bit definitions

Bit Position	Field Description	Value Description
0	Broadcast Packet Filter status	0b = Disabled 1b = Enabled
1	Channel Enabled	0b = Disabled 1b = Enabled
2	Channel Network TX Enabled	0b = Disabled 1b = Enabled
3	Global Multicast Packet Filter Status	0b = Disabled 1b = Enabled
4..31	Reserved	Reserved

2292 **8.4.49 Get Controller Packet Statistics command (0x18)**

2293 The Get Controller Packet Statistics command may be used by the Management Controller to request a
 2294 copy of the aggregated packet statistics that the channel maintains for its external interface to the LAN
 2295 network. The statistics are an aggregation of statistics for both the host side traffic and the NC-SI Pass-
 2296 through traffic.

2297

Table 94 – Get Controller Packet Statistics command packet format

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

2298 **8.4.50 Get Controller Packet Statistics response (0x98)**

2299 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get
 2300 Controller Packet Statistics command and send the response packet shown in Table 95.

2301 The Get Controller Packet Statistics Response frame contains a set of statistics counters that monitor the
 2302 LAN traffic in the Network Controller. Implementation of the counters listed in Table 96 is optional. The

2303 Network Controller shall return any unsupported counter with a value of 0xFFFFFFFF for 32-bit counters
 2304 and 0xFFFFFFFFFFFFFFFF for 64-bit counters.

2305 **Table 95 – Get Controller Packet Statistics response packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00

2306

Table 96 – Get Controller Packet Statistics counters

Counter Number	Name	Meaning
0	Total Bytes Received	Counts the number of bytes received
1	Total Bytes Transmitted	Counts the number of bytes transmitted
2	Total Unicast Packets Received	Counts the number of good (FCS valid) packets received that passed L2 filtering by a specific MAC address
3	Total Multicast Packets Received	Counts the number of good (FCS valid) multicast packets received
4	Total Broadcast Packets Received	Counts the number of good (FCS valid) broadcast packets received
5	Total Unicast Packets Transmitted	Counts the number of good (FCS valid) packets transmitted that passed L2 filtering by a specific MAC address
6	Total Multicast Packets Transmitted	Counts the number of good (FCS valid) multicast packets transmitted
7	Total Broadcast Packets Transmitted	Counts the number of good (FCS valid) broadcast packets transmitted
8	FCS Receive Errors	Counts the number of receive packets with FCS errors
9	Alignment Errors	Counts the number of receive packets with alignment errors
10	False Carrier Detections	Counts the false carrier errors reported by the PHY

Counter Number	Name	Meaning
11	Runt Packets Received	Counts the number of received frames that passed address filtering, were less than minimum size (64 bytes from <Destination Address> through <FCS>, inclusively), and had a valid FCS
12	Jabber Packets Received	Counts the number of received frames that passed address filtering, were greater than the maximum size, and had a valid FCS
13	Pause XON Frames Received	Counts the number of XON packets received from the network
14	Pause XOFF Frames Received	Counts the number of XOFF packets received from the network
15	Pause XOFF Frames Transmitted	Counts the number of XON packets transmitted to the network
16	Pause XOFF Frames Transmitted	Counts the number of XOFF packets transmitted to the network
17	Single Collision Transmit Frames	Counts the number of times that a successfully transmitted packet encountered a single collision
18	Multiple Collision Transmit Frames	Counts the number of times that a transmitted packet encountered more than one collision but fewer than 16
19	Late Collision Frames	Counts the number of collisions that occurred after one slot time (defined by IEEE 802.3)
20	Excessive Collision Frames	Counts the number of times that 16 or more collisions occurred on a single transmit packet
21	Control Frames Received	Counts the number of MAC control frames received that are <i>not</i> XON or XOFF flow control frames
22	64 Byte Frames Received	Counts the number of good packets received that are exactly 64 bytes (from <Destination Address> through <FCS>, inclusively) in length
23	65–127 Byte Frames Received	Counts the number of good packets received that are 65–127 bytes (from <Destination Address> through <FCS>, inclusively) in length
24	128–255 Byte Frames Received	Counts the number of good packets received that are 128–255 bytes (from <Destination Address> through <FCS>, inclusively) in length
25	256–511 Byte Frames Received	Counts the number of good packets received that are 256–511 bytes (from <Destination Address> through <FCS>, inclusively) in length
26	512–1023 Byte Frames Received	Counts the number of good packets received that are 512–1023 bytes (from <Destination Address> through <FCS>, inclusively) in length
27	1024–1522 Byte Frames Received	Counts the number of good packets received that are 1024–1522 bytes (from <Destination Address> through <FCS>, inclusively) in length

Counter Number	Name	Meaning
28	1523–9022 Byte Frames Received	Counts the number of received frames that passed address filtering and were greater than 1523 bytes in length
29	64 Byte Frames Transmitted	Counts the number of good packets transmitted that are exactly 64 bytes (from <Destination Address> through <FCS>, inclusively) in length
30	65–127 Byte Frames Transmitted	Counts the number of good packets transmitted that are 65–127 bytes (from <Destination Address> through <FCS>, inclusively) in length
31	128–255 Byte Frames Transmitted	Counts the number of good packets transmitted that are 128–255 bytes (from <Destination Address> through <FCS>, inclusively) in length
32	256–511 Byte Frames Transmitted	Counts the number of good packets transmitted that are 256–511 bytes (from <Destination Address> through <FCS>, inclusively) in length
33	512–1023 Byte Frames Transmitted	Counts the number of good packets transmitted that are 512–1023 bytes (from <Destination Address> through <FCS>, inclusively) in length
34	1024–1522 Byte Frames Transmitted	Counts the number of good packets transmitted that are 1024–1522 bytes (from <Destination Address> through <FCS>, inclusively) in length
35	1523–9022 Byte Frames Transmitted	Counts the number of transmitted frames that passed address filtering and were greater than 1523 in length
36	Valid Bytes Received	Counts the bytes received in all packets that did not manifest any type of error
37	Error Runt Packets Received	Counts the number of invalid frames that were less than the minimum size (64 bytes from <Destination Address> through <FCS>, inclusively)
38	Error Jabber Packets Received	Counts Jabber packets, which are defined as packets that exceed the programmed MTU size <i>and</i> have a bad FCS value

2307 The Network Controller shall also indicate in the Counters Cleared from Last Read fields whether the
 2308 corresponding field has been cleared by means other than NC-SI (possibly by the host) since it was last
 2309 read by means of the NC-SI. Counting shall resume from 0 after a counter has been cleared. The
 2310 Counters Cleared from Last Read fields format is shown in Table 97.

2311 Currently no command-specific reason code is identified for this response.

2312 **Table 97 – Counters Cleared from Last Read Fields format**

Field	Bits	Mapped to Counter Numbers
MS Bits	0..6	32..38
	7..31	Reserved
LS Bits	0..31	0..31

2313 IMPLEMENTATION NOTE The Get Controller Packet Statistics response contains the following counters related
 2314 to flow control: Pause XON Frames Received, Pause XOFF Frames Received, Pause XON Frames Transmitted, and
 2315 Pause XOFF Frames Transmitted. An implementation can optionally include Priority-Based Flow Control (PFC)
 2316 packets in these counters.

2317 **8.4.51 Get NC-SI Statistics command (0x19)**

2318 In addition to the packet statistics accumulated on the LAN network interface, the channel separately
 2319 accumulates a variety of NC-SI specific packet statistics for the channel. The Get NC-SI Statistics
 2320 command may be used by the Management Controller to request that the channel send a copy of all
 2321 current NC-SI packet statistic values for the channel. The implementation may or may not include
 2322 statistics for commands that are directed to the package.

2323 Table 98 illustrates the packet format of the Get NC-SI Statistics command.

2324 **Table 98 – Get NC-SI Statistics command packet format**

		Bits			
Bytes		31..24	23..16	15..08	07..00
00..15		NC-SI Header			
16..19		Checksum			
20..45		Pad			

2325 **8.4.52 Get NC-SI Statistics response (0x99)**

2326 In the absence of any error, the channel shall process and respond to the Get NC-SI Statistics command
 2327 by sending the response packet and payload shown in Table 99.

2328 **Table 99 – Get NC-SI Statistics response packet format**

		Bits			
Bytes		31..24	23..16	15..08	07..00
00..15		NC-SI Header			
16..19		Response Code		Reason Code	
20..23		NC-SI Commands Received			
24..27		NC-SI Control Packets Dropped			
28..31		NC-SI Command Type Errors			
32..35		NC-SI Command Checksum Errors			
36..39		NC-SI Receive Packets			
40..43		NC-SI Transmit Packets			
44..47		AENs Sent			
48..51		Checksum			

2329 The Get NC-SI Statistics Response frame contains a set of statistics counters that monitor the NC-SI
 2330 traffic in the Network Controller. Counters that are supported shall be reset to 0x0 when entering into the
 2331 Initial State and after being read. Implementation of the counters shown in Table 100 is optional. The
 2332 Network Controller shall return any unsupported counter with a value of 0xFFFFFFFF. Counters may
 2333 wraparound or stop if they reach 0xFFFFFFFFE. It is vendor specific how NC-SI commands that are sent
 2334 to the package ID are included in the NC-SI statistics.

2335 Currently no command-specific reason code is identified for this response.

2336

Table 100 – Get NC-SI Statistics counters

Counter Number	Name	Meaning
1	NC-SI Commands Received	For packets that are not dropped, this field returns the number of NC-SI Control packets received and identified as NC-SI commands.
2	NC-SI Control Packets Dropped	Counts the number of NC-SI Control packets that were received and dropped (Packets with correct FCS and EtherType, but are dropped for one of the other reasons listed in 6.9.2.1). NC-SI Control Packets that were dropped because the channel ID was not valid may not be included in this statistics counter.
3	NC-SI Unsupported Commands Received	Counts the number of NC-SI command packets that were received, but are not supported. (Network controller responded to the command with a Command Unsupported response code).
4	NC-SI Command Checksum Errors	Counts the number of NC-SI Control Packets that were received but dropped because of an invalid checksum (if checksum is provided and checksum validation is supported by the channel)
5	NC-SI Receive Packets	Counts the total number of NC-SI Control packets received. This count is the sum of NC-SI Commands Received and NC-SI Control Packets Dropped.
6	NC-SI Transmit Packets	Counts the total number of NC-SI Control packets transmitted to the Management Controller. This count is the sum of NC-SI responses sent and AENs sent.
7	AENs Sent	Counts the total number of AEN packets transmitted to the Management Controller

2337 **8.4.53 Get NC-SI Pass-through Statistics command (0x1A)**

2338 The Get NC-SI Pass-through Statistics command may be used by the Management Controller to request
 2339 that the channel send a copy of all current NC-SI Pass-through packet statistic values.

2340 Table 101 illustrates the packet format of the Get NC-SI Pass-through Statistics command.

2341 **Table 101 – Get NC-SI Pass-through Statistics command packet format**

		Bits			
Bytes		31..24	23..16	15..08	07..00
00..15	NC-SI Header				
16..19	Checksum				
20..45	Pad				

2342 **8.4.54 Get NC-SI Pass-through Statistics response (0x9A)**

2343 In the absence of any error, the channel shall process and respond to the Get NC-SI Pass-through
 2344 Statistics command by sending the response packet and payload shown in Table 102.

2345 **Table 102 – Get NC-SI Pass-through Statistics response packet format**

		Bits			
Bytes		31..24	23..16	15..08	07..00
00..15	NC-SI Header				
16..19	Response Code		Reason Code		
20..27	Pass-through TX Packets Received on NC-SI Interface (Management Controller to Network Controller)				
28..31	Pass-through TX Packets Dropped				
32..35	Pass-through TX Packet Channel State Errors				
36..39	Pass-through TX Packet Undersized Errors				
40..43	Pass-through TX Packet Oversized Errors				
44..47	Pass-through RX Packets Received on LAN Interface				
48..51	Total Pass-through RX Packets Dropped				
52..55	Pass-through RX Packet Channel State Errors				
56..59	Pass-through RX Packet Undersized Errors				
60..63	Pass-through RX Packet Oversized Errors				
64..67	Checksum				

2346 The Get NC-SI Statistics Response frame contains a set of statistics counters that monitor the NC-SI
 2347 Pass-through traffic in the Network Controller. Supported counters shall be reset to 0x0 when entering
 2348 the Initial State and after being read. Implementation of the counters shown in Table 103 is optional. The
 2349 Network Controller shall return any unsupported counter with a value of 0xFFFFFFFF for 32-bit counters

2350 and 0xFFFFFFFFFFFFFFFF for 64-bit counters. Counters may wraparound or stop if they reach
 2351 0xFFFFFFFF for 32-bit counters and 0xFFFFFFFFFFFFFFFF for 64-bit counters.

2352 **Table 103 – Get NC-SI Pass-through Statistics counters**

Counter Number	Name	Meaning
1	Total Pass-through TX Packets Received (Management Controller to Channel)	Counts the number of Pass-through packets forwarded by the channel to the LAN
2	Total Pass-through TX Packets Dropped (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were dropped by the Network Controller
3	Pass-through TX Packet Channel State Errors (Management Controller to Channel)	Counts the number of egress management packets (Management Controller to Network Controller) that were dropped because the channel was in the disabled state when the packet was received
4	Pass-through TX Packet Undersized Errors (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were undersized (under 64 bytes, including FCS)
5	Pass-through TX Packet Oversized Errors (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were oversized (over 1522 bytes, including FCS)
6	Total Pass-through RX Packets Received On the LAN Interface (LAN to Channel)	Counts the number of Pass-through packets that were received on the LAN interface of the channel. This counter does not necessarily count the number of packets that were transmitted to the Management Controller, because some of the packets might have been dropped due to RX queue overflow.
7	Total Pass-through RX Packets Dropped (LAN to Channel)	Counts the number of Pass-through packets that were received on the LAN interface of the channel but were dropped and not transmitted to the Management Controller
8	Pass-through RX Packet Channel State Errors (LAN to Channel)	Counts the number of ingress management packets (channel to Management Controller) that were dropped because the channel was in the disabled state when the packet was received. The NC may also count packets that were dropped because the package was in the deselected state.
9	Pass-through RX Packet Undersized Errors (LAN to Channel)	Counts the number of Pass-through packets from the LAN that were undersized (under 64 bytes, including FCS)
10	Pass-through RX Packet Oversized Errors (LAN to Channel)	Counts the number of Pass-through packets from the LAN that were oversized (over 1522 bytes, including FCS)

2353 Currently no command-specific reason code is identified for this response.

2354 **8.4.55 Get Package Status command (0x1B)**

2355 The Get Package Status command provides a way for a Management Controller to explicitly query the
 2356 status of a package. The Get Package Status command is addressed to the package, rather than to a

2357 particular channel (that is, the command is sent with a Channel ID where the Package ID subfield
 2358 matches the ID of the intended package and the Internal Channel ID subfield is set to 0x1F).

2359 Table 104 illustrates the packet format of the Get Package Status command.

2360 **Table 104 – Get Package Status packet format**

Bytes		Bits			
Bytes	31..24	23..16	15..08	07..00	
00..15	NC-SI Header				
20..23	Checksum				
24..45	Pad				

2361 **8.4.56 Get Package Status response (0x9B)**

2362 Currently no command-specific reason code is identified for this response (see Table 24).

2363 **Table 105 – Get Package Status response packet format**

Bytes		Bits			
Bytes	31..24	23..16	15..08	07..00	
00..15	NC-SI Header				
16..19	Response Code		Reason Code		
20..23	Package Status				
24..27	Checksum				
28..45	Pad				

2364 **Table 106 – Package Status field bit definitions**

Bit Position	Field Description	Value Description
0	Hardware Arbitration Status	0b = Hardware arbitration is non-operational (inactive) or unsupported. NOTE This means that hardware arbitration tokens are not flowing through this NC. 1b = Hardware arbitration is supported, active, and implemented for the package on the given system.
31..1	Reserved	Reserved

2365 **8.4.57 OEM command (0x50)**

2366 The OEM command may be used by the Management Controller to request that the channel provide
 2367 vendor-specific information. The [Vendor Enterprise Number](#) is the unique MIB/SNMP Private Enterprise
 2368 number assigned by IANA per organization. Vendors are free to define their own internal data structures
 2369 in the vendor data fields. Use of the optional checksum field is unspecified in OEM commands.

2370 Table 107 illustrates the packet format of the OEM command.

2371 **Table 107 – OEM command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Manufacturer ID (IANA)			
20...	Vendor-Data			

2372 **8.4.58 OEM response (0xD0)**

2373 The channel shall return the “Unknown Command Type” reason code for any unrecognized enterprise
 2374 number, using the packet format shown in Table 108. If the command is valid, the response, if any, is
 2375 allowed to be vendor-specific. The 0x8000 range is recommended for vendor-specific code. Use of the
 2376 optional checksum field is unspecified in OEM responses.

2377 Currently no command-specific reason code is identified for this response.

2378

2379 **Table 108 – OEM response packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (IANA)			
24...	Return Data (Optional)			

2380 **8.4.59 PLDM Request (0x51)**

2381 The PLDM Request Message may be used by the Management Controller to send PLDM commands
 2382 over NC-SI/RBT. This command may be targeted at the entire package or a specific channel.

2383 Table 109 illustrates the packet format of the PLDM Request Message over NC-SI/RBT.

2384 **Table 109 – PLDM Request packet format**

Bits	
Bytes	31..24 23..16 15..08 07..00
00..15	NC-SI Header
16..19	PLDM Message Common Fields
20..	PLDM Message Payload (zero or more bytes) + Payload Pad (see 8.2.2.2)
..	Checksum
..	Ethernet Packet Pad (optional – See 8.2.2.4)

2385 Refer to the PLDM Base specification (DSP0240) for details on the PLDM Request Messages.

2386 **8.4.60 PLDM Response (0xD1)**

2387 The PLDM Response Message may be used by the Network Controller to send PLDM responses over
 2388 NC-SI/RBT. The package shall, in the absence of a checksum error or identifier mismatch, always accept
 2389 the PLDM Request Command and send a response.

2390 **Table 110 – PLDM Response packet format**

Bits	
Bytes	31..24 23..16 15..08 07..00
00..15	NC-SI Header
16..19	Response Code Reason Code
20..23	PLDM Message Common Fields PLDM Completion Code
24..	PLDM Message Payload (zero or more bytes) + Payload Pad (see 8.2.2.2)
..	Checksum
..	Ethernet Packet Pad (optional – See 8.2.2.4)

2391 Refer to the PLDM Base specification (DSP0240) for details on the PLDM Response Messages.

2392 Note, the NC-SI PLDM Response (0xD1) response/reason codes are only used to report the support,
 2393 success, or failure of the PLDM Request command (0x51) at the NC-SI over RBT messaging layer. The
 2394 PLDM Completion Code is used for determining the success or failure of the encapsulated PLDM
 2395 Commands at the PLDM messaging layer.

2396 **8.4.61 Get Package UUID command (0x52)**

2397 The Get Package UUID command may be used by the Management Controller to query Universally
 2398 Unique Identifier (UUID), also referred to as a globally unique ID (GUID), of the Network Controller over
 2399 NC-SI/RBT. This command is targeted at the entire package. This command can be used by the MC to
 2400 correlate endpoints used on different NC-SI transports (e.g. RBT, MCTP).

2401 Table 111 illustrates the packet format of the Get Package UUID Command over NC-SI/RBT.

2402 **Table 111 – Get Package UUID command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

2403 **8.4.62 Get Package UUID response (0xD2)**

2404 The package shall, in the absence of an error, always accept the Get Package UUID command and send
 2405 the response packet shown in Table 112. Currently no command-specific reason code is identified for this
 2406 response.

2407 **Table 112 – Get Package UUID response packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..35	UUID bytes 1:16, respectively			
36..39	Checksum			
40..45	Pad			

2408 The individual fields within the UUID are stored most-significant byte (MSB) first per the convention
 2409 described in RFC4122. RFC4122 specifies four different versions of UUID formats and generation
 2410 algorithms suitable for use for a UUID. These are version 1 (0001b) "time based", and three "name-
 2411 based" versions: version 3 (0011b) "MD5 hash", version 4 (0100b) "Pseudo-random", and version 5
 2412 "SHA1 hash". The version 1 format is recommended. However, versions 3, 4, or 5 formats are also
 2413 allowed. See Table 113 for the UUID format version 1.

2414

2415

Table 113 – UUID Format

Field	UUID Byte	MSB
time low	1	MSB
	2	
	3	
	4	
time mid	5	MSB
	6	
time high and version	7	MSB
	8	
clock seq and reserved	9	MSB

2416 **8.5 AEN packet formats**

2417 **8.5.1 Link Status Change AEN**

2418 The Link Status Change AEN indicates to the Management Controller any changes in the channel's
 2419 external interface link status.

2420 This AEN should be sent if any change occurred in the link status (that is, the actual link mode was
 2421 changed). The Link Status and OEM Link Status fields reproduce the bit definitions defined in the Get
 2422 Link Status Response Packet (see Table 47).

2423 Table 114 illustrates the packet format of the Link Status Change AEN.

2424 **Table 114 – Link Status Change AEN packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x00
20..23	Link Status			
24..27	OEM Link Status			
28..31	Checksum			

2425 **8.5.2 Configuration Required AEN**

2426 The Configuration Required AEN indicates to the Management Controller that the channel is transitioning
 2427 into the Initial State. (This AEN is not sent if the channel enters the Initial State because of a Reset
 2428 Channel command.)

2429 NOTE This AEN might not be generated in some situations in which the channel goes into the Initial State. For
 2430 example, some types of hardware resets might not accommodate generating the AEN.

2431 Table 115 illustrates the packet format of the Configuration Required AEN.

2432 **Table 115 – Configuration Required AEN packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x01
20..23	Checksum			

2433 **8.5.3 Host Network Controller Driver Status Change AEN**

2434 This AEN indicates a change of the Host Network Controller Driver Status. Table 116 illustrates the
 2435 packet format of the AEN.

2436 **Table 116 – Host Network Controller Driver Status Change AEN packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x02
20..23	Host Network Controller Driver Status			
24..27	Checksum			

2437 The Host Network Controller Driver Status field has the format shown in Table 117.

2438 **Table 117 – Host Network Controller Driver Status format**

Bit Position	Name	Description
0	Host Network Controller Driver Status	0b = The Network Controller driver for the host external network interface associated with this channel is not operational (not running). 1b = The Network Controller driver for the host external network interface associated with this channel is being reported as operational (running).
1..31	Reserved	Reserved

2439 **9 Packet-based and op-code timing**

2440 Table 118 presents the timing specifications for a variety of packet-to-electrical-buffer interactions, inter-
 2441 packet timings, and op-code processing requirements. The following timing parameters shall apply to NC-
 2442 SI over RBT binding defined in this specification.

2443 **Table 118 – NC-SI packet-based and op-code timing parameters**

Name	Symbol	Value	Description
Package Deselect to Hi-Z Interval	T1	200 μ s, max	Maximum time interval from when a Network Controller completes transmitting the response to a Deselect Package command to when the Network Controller outputs are in the high-impedance state Measured from the rising edge of the first clock that follows the last bit of the packet to when the output is in the high-impedance state as defined in clause 10
Package Output to Data	T2	2 clocks, min	Minimum time interval after powering up the output drivers before a Network Controller starts transmitting a packet through the NC-SI interface Measured from the rising edge of the first clock of the packet
Network Controller Power Up Ready Interval	T4	2 s, max	Time interval from when the NC-SI on a Network Controller is powered up to when the Network Controller is able to respond to commands over the NC-SI Measured from when V_{ref} becomes available
Normal Execution Interval	T5	50 ms, max	Maximum time interval from when a controller receives a command to when it delivers a response to that command, unless otherwise specified Measured from the rising edge of the first clock following the last bit of the command packet to the rising edge of the clock for the first bit of the response packet
Asynchronous Reset Interval	T6	2 s, max	Interval during which a controller is allowed to not recognize or respond to commands due to an Asynchronous Reset event For a Management Controller, this means that a Network Controller could become unresponsive for up to T6 seconds if an Asynchronous Reset event occurs. This is not an error condition. The Management Controller retry behavior should be designed to accommodate this possibility.
Synchronous Reset Interval	T7	2 s, max	Interval during which a controller may not recognize or respond to requests due to a Synchronous Reset event Measured from the rising edge of the first clock following the last bit of the Reset Channel response packet
Token Timeout	T8	32,000 REF_CLK min	Number of REF_CLKs before timing out while waiting for a TOKEN to be received

Name	Symbol	Value	Description
Op-Code Processing	T9	32 REF_CLK max	Number of REF_CLKs after receiving an op-code on ARB_IN to decode the op-code and generate the next op-code on ARB_OUT Measured from the falling edge of the last bit of the op-code received on ARB_IN to the rising edge of the next op-code on ARB_OUT
Op-Code Bypass Delay	T10	32 REF_CLK max	Number of REF_CLK delays between a bit received on ARB_IN and the corresponding bit passed on to ARB_OUT while in Bypass Mode Measured from the falling edge of the last bit of the op-code received on ARB_IN to the rising edge of the next op-code on ARB_OUT
TOKEN to RXD	T11	T2 min, 32 REF_CLK max	Number of REF_CLKs after receiving TOKEN to when packet data is driven onto the RXD lines Measured from the falling edge of the last bit of the op-code received on ARB_IN to the rising edge of the next op-code on ARB_OUT
Max XOFF Renewal Interval	T12	50,331,648 REF_CLK max	Maximum time period (3 XOFF Frame timer cycles) during which a channel within a package is allowed to request and renew a single XOFF condition after requesting the initial XOFF
IPG to TOKEN Op-code Overlap	T13	6 REF_CLK max	Maximum number of REF_CLKs that the beginning of TOKEN transmission can precede the end of the Inter Packet Gap. For more information, see 7.3.8.
NOTE If hardware arbitration is in effect, the hardware arbitration output buffer enable/disable timing specifications take precedence.			

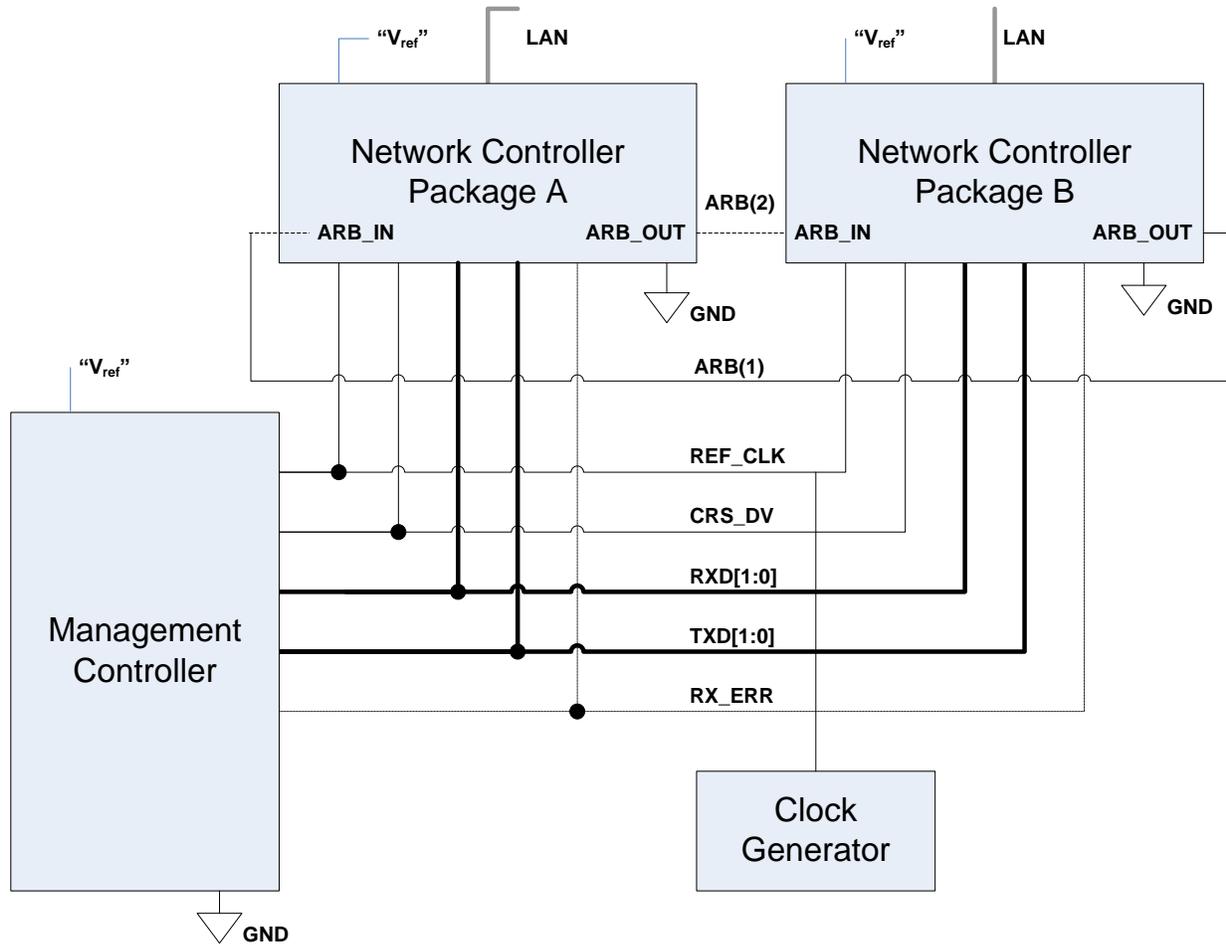

2444 10 RBT Electrical specification

2445

2446 10.1 Topologies

2447 The electrical specification defines the NC-SI electrical characteristics for one management processor
 2448 and one to four Network Controller packages in a bussed “multi-drop” arrangement. The actual number of
 2449 devices that can be supported may differ based on the trace characteristics and routing used to
 2450 interconnect devices in an implementation.

2451 Figure 16 shows an example topology.

2452

2453

Figure 16 – Example NC-SI signal interconnect topology

2454

10.2 Electrical and signal characteristics and requirements

2455

2456

10.2.1 Companion specifications

2457

Implementations of the physical interface and signaling for the NC-SI shall meet the specifications in [RMII](#)

2458

and [IEEE 802.3](#), except where those requirements differ or are extended with specifications provided in

2459

this document, in which case the specifications in this document shall take precedence.

2460

10.2.2 Full-duplex operation

2461

NC-SI RBT is specified only for full-duplex operation. Half-duplex operation is not covered by this

2462

specification.

2463 **10.2.3 Signals**

2464 Table 119 lists the signals that make up the NC-SI physical interface.

2465 Unless otherwise specified, the high level of an NC-SI signal corresponds to its asserted state, and the
 2466 low level represents the de-asserted state. For data bits, the high level represents a binary '1' and the low
 2467 level a binary '0'.

2468 **Table 119 – Physical NC-SI signals**

Signal Name	Direction (with respect to the Network Controller)	Direction (with respect to the Management Controller MAC)	Use	Mandatory or Optional
REF_CLK ^[a]	Input	Input	Clock reference for receive, transmit, and control interface	M
CRS_DV ^[b]	Output	Input	Carrier Sense/Receive Data Valid	M
RXD[1:0]	Output	Input	Receive data	M
TX_EN	Input	Output	Transmit enable	M
TXD[1:0]	Input	Output	Transmit data	M
RX_ER	Output	Input	Receive error	O
ARB_IN	Input ^[c]	N/A	Network Controller hardware arbitration Input	O ^[c]
ARB_OUT	Output ^[c]	N/A	Network Controller hardware arbitration Output	O ^[c]

^[a] A device can provide an additional option to allow it to be configured as the source of REF_CLK, in which case the device is not required to provide a separate REF_CLK input line, but it can use REF_CLK input pin as an output. The selected configuration shall be in effect at NC-SI power up and remain in effect while the NC-SI is powered up.

^[b] In the [RMII Specification](#), the MII Carrier Sense signal, CRS, was combined with RX_DV to form the CRS_DV signal. When the NC-SI is using its specified full-duplex operation, the CRS aspect of the signal is not required; therefore, the signal shall provide only the functionality of RX_DV as defined in [IEEE 802.3](#). (This is equivalent to the CRS_DV signal states in [RMII Specification](#) when a carrier is constantly present.) The Carrier Sense aspect of the CRS_DV signal is not typically applicable to the NC-SI because it does not typically detect an actual carrier (unlike an actual PHY). However, the Network Controller should emulate a carrier-present status on CRS_DV per [IEEE 802.3](#) in order to support Management Controller MACs that may require a carrier-present status for operation.

^[c] If hardware arbitration is implemented, the Network Controller package shall provide both ARB_IN and ARB_OUT connections. In some implementations, ARB_IN may be required to be tied to a logic high or low level if it is not used.

2469 **10.2.4 High-impedance control**

2470 Shared NC-SI operation requires Network Controller devices to be able to set their NC-SI outputs
 2471 (RXD[1:0], CRS_DV, and, if implemented, RX_ER) into a high-impedance state either upon receipt of a
 2472 command received through NC-SI, or, if hardware-based arbitration is in effect, as a result of hardware-
 2473 based arbitration. A pull-down resistor should be provided on high impedance lines in a way that will keep
 2474 the C_{load} value so that the line won't float.

2475 Network Controller packages shall leave their NC-SI outputs in the high-impedance state on interface
 2476 power up and shall not drive their NC-SI outputs until selected. For additional information about Network
 2477 Controller packages, see 8.4.5.

2478 For NC-SI output signals in this specification, unless otherwise specified, the high-impedance state is
 2479 defined as the state in which the signal leakage meets the I_z specification provided in 10.2.5.

2480 10.2.5 DC characteristics

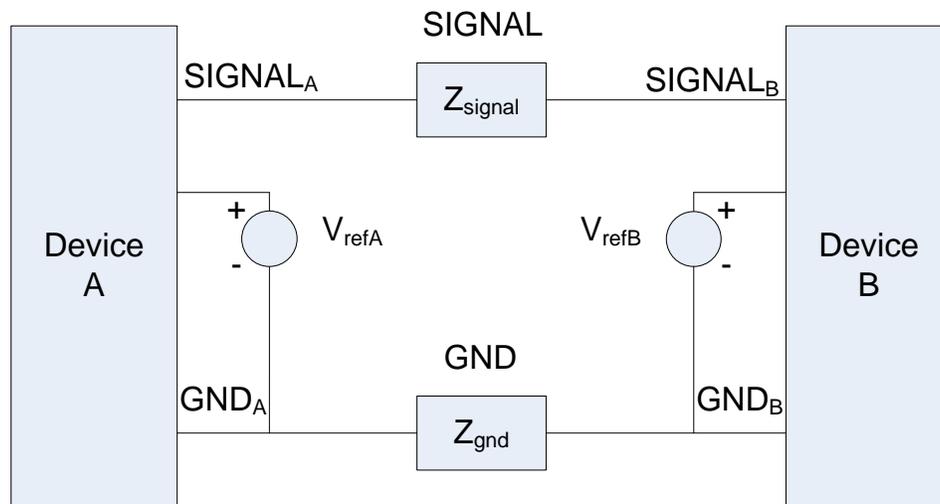

2481 This clause defines the DC characteristics of the NC-SI physical interface.

2482 10.2.5.1 Signal levels

2483 CMOS 3.3 V signal levels are used for this specification.

2484 The following characteristics apply to DC signals:

- 2485 • Unless otherwise specified, DC signal levels and V_{ref} are measured relative to Ground (GND) at
 2486 the respective device providing the interface, as shown in Figure 17.
- 2487 • Input specifications refer to the signals that a device shall accept for its input signals, as
 2488 measured at the device.
- 2489 • Output specifications refer to signal specifications that a device shall emit for its output signals,
 2490 as measured at the device.

2491

2492

Figure 17 – DC measurements

2493 Table 120 provides DC specifications.

2494 **Table 120 – DC specifications**

Parameter	Symbol	Conditions	Minimum	Typical	Maximum	Units
IO reference voltage	V_{ref} ^[a]		3.0	3.3	3.6	V
Signal voltage range	V_{abs}		-0.300		3.765	V
Input low voltage	V_{il}				0.8	V
Input high voltage	V_{ih}		2.0			V
Input high current	I_{ih}	$V_{in} = V_{ref} = V_{ref,max}$	0		200	μA
Input low current	I_{il}	$V_{in} = 0 V$	-20		0	μA
Output low voltage	V_{ol}	$I_{ol} = 4 mA, V_{ref} = min$	0		400	mV
Output high voltage	V_{oh}	$I_{oh} = -4 mA, V_{ref} = min$	2.4		V_{ref}	V
Clock midpoint reference level	V_{ckm}				1.4	V
Leakage current for output signals in high-impedance state	I_z	$0 \leq V_{in} \leq V_{ref}$ at $V_{ref} = V_{ref,max}$	-20		20	μA

^[a] V_{ref} = Bus high reference level (typically the NC-SI logic supply voltage). This parameter replaces the term *supply voltage* because actual devices may have internal mechanisms that determine the operating reference for the NC-SI that are different from the devices' overall power supply inputs.

V_{ref} is a reference point that is used for measuring parameters (such as overshoot and undershoot) and for determining limits on signal levels that are generated by a device. In order to facilitate system implementations, a device shall provide a mechanism (for example, a power supply pin, internal programmable reference, or reference level pin) to allow V_{ref} to be set to within 20 mV of any point in the specified V_{ref} range. This approach enables a system integrator to establish an interoperable V_{ref} level for devices on the NC-SI.

2495 10.2.6 AC characteristics

2496 This clause defines the AC characteristics of the NC-SI physical interface.

2497 10.2.6.1 Rise and fall time measurement

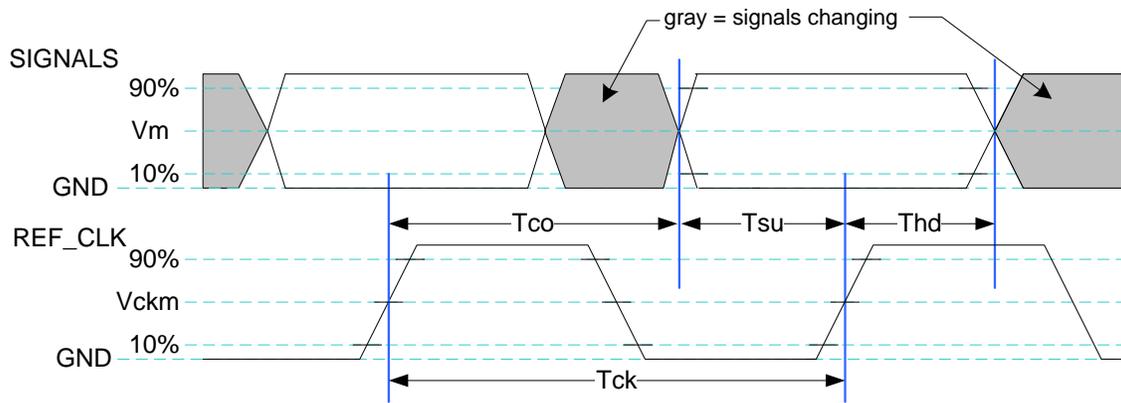

2498 Rise and fall time are measured between points that cross 10% and 90% of V_{ref} (see Table 120). The
2499 middle points (50% of V_{ref}) are marked as V_{ckm} and V_m for clock and data, respectively.

2500 10.2.6.2 REF_CLK measuring points

2501 In Figure 18, REF_CLK duty cycle measurements are made from V_{ckm} to V_{ckm} . Clock skew T_{skew} is
2502 measured from V_{ckm} to V_{ckm} of two NC-SI devices and represents maximum clock skew between any two
2503 devices in the system.

2504 10.2.6.3 Data, control, and status signal measuring points

2505 In Figure 18, all timing measurements are made between V_{ckm} and V_m . T_{co} is measured with a capacitive
2506 load between 10 pF and 50 pF. Propagation delay T_{prop} is measured from V_m on the transmitter to V_m on
2507 the receiver.

2508

2509

Figure 18 – AC measurements

2510 Table 121 provides AC specifications.

2511

Table 121 – AC specifications

Parameter	Symbol	Minimum	Typical	Maximum	Units
REF_CLK Frequency			50	50+100 ppm	MHz
REF_CLK Duty Cycle		35		65	%
Clock-to-out ^[a] (10 pF ≤ C _{load} ≤ 50 pF)	T _{co}	2.5		12.5	ns
Skew between clocks	T _{skew}			1.5	ns
TXD[1:0], TX_EN, RXD[1:0], CRS_DV, RX_ER, and ARB_IN data setup to REF_CLK rising edge	T _{su}	3			ns
TXD[1:0], TX_EN, RXD[1:0], CRS_DV, RX_ER, and ARB_OUT data hold from REF_CLK rising edge	T _{hd}	1			ns
Signal Rise/Fall Time	T _r /T _f	0.5		6	ns
REF_CLK Rise/Fall Time	T _{ckr} /T _{ckf}	0.5		3.5	ns
Interface Power-Up High-Impedance Interval	T _{pwz}	2			μs
Power Up Transient Interval (recommendation)	T _{pwrt}			100	ns
Power Up Transient Level (recommendation)	V _{pwrt}	-200		200	mV
Interface Power-Up Output Enable Interval	T _{pwre}			10	ms
EXT_CLK Startup Interval	T _{clkstrt}			100	ms

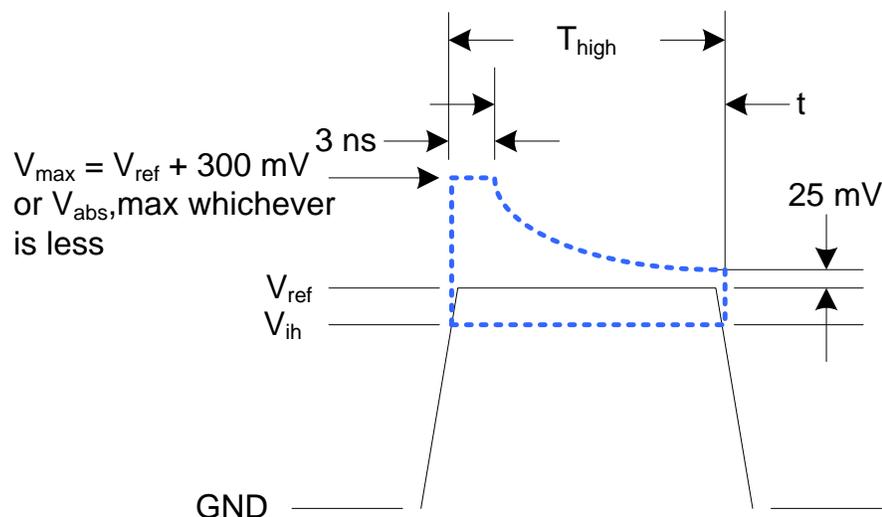

^[a] This timing relates to the output pins, while T_{su} and T_{hd} relate to timing at the input pins.

2512 **10.2.6.4 Timing calculation (informative)**2513 **10.2.6.4.1 Setup time calculation**

2514
$$T_{su} \leq T_{clk} - (T_{skew} + T_{co} + T_{prop})$$

2515 **10.2.6.4.2 Hold time calculation**

2516
$$T_{hd} \leq T_{co} - T_{skew} + T_{prop}$$

2517 **10.2.6.5 Overshoot specification**2518 Devices shall accept signal overshoot within the ranges specified in Figure 19, measured at the device,
2519 without malfunctioning.

2520

2521

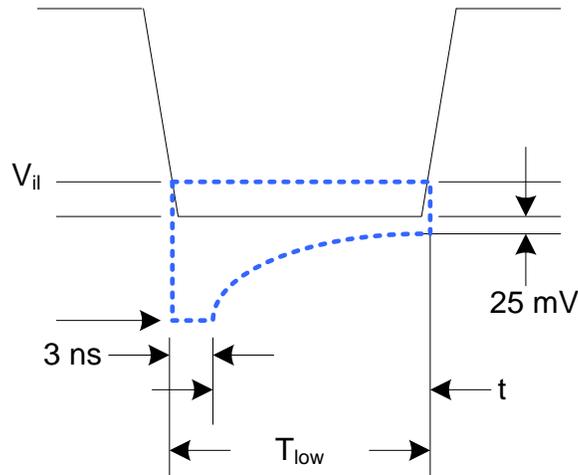

Figure 19 – Overshoot measurement2522 The signal is allowed to overshoot up to the specified V_{max} for the first 3 ns following the transition above
2523 V_{ih} . Following that interval is an exponential decay envelope equal to the following:

2524
$$V_{ref} + V_{os} * e^{-K * ([t - 3 \text{ ns}] / T_d)}$$

2525 Where, for $t = 3$ to 10 ns:2526 $t = 0$ corresponds to the leading crossing of V_{ih} , going high.2527 V_{ref} is the bus high reference voltage (see 10.2.5).2528 $V_{abs,max}$ is the maximum allowed signal voltage level (see 10.2.5).2529 $V_{os} = V_{max} - V_{ref}$ 2530 $K = \ln(25 \text{ mV} / V_{os})$ 2531 $T_d = 7 \text{ ns}$ 2532 For $t > 10 \text{ ns}$, the $V_{ref} + 25 \text{ mV}$ limit holds flat until the conclusion of T_{high} .

2533 **10.2.6.6 Undershoot specification**

2534 Devices are required to accept signal undershoot within the ranges specified in Figure 20, measured at
 2535 the device, without malfunctioning.

2536

2537 **Figure 20 – Undershoot measurement**

2538 The signal is allowed to undershoot up to the specified $V_{abs,min}$ for the first 3 ns following the transition
 2539 above V_{ii} . Following that interval is an exponential envelope equal to the following:

$$2540 \quad * ([t - 3 \text{ ns}] / T_d)$$

2541 Where, for $t = 3$ to 10 ns:

2542 $t = 0$ corresponds to the leading crossing of V_{ii} , going low.

2543 $V_{abs,min}$ is the minimum allowed signal voltage level (see 10.2.5).

$$2544 \quad K = \ln(25 \text{ mV} / V_{os})$$

$$2545 \quad T_d = 7 \text{ ns}$$

2546 For $t > 7$ ns, the GND – 25 mV limit holds flat until the conclusion of T_{low} .

2547 **10.2.7 Interface power-up**

2548 To prevent signals from back-powering unpowered devices, it is necessary to specify a time interval
 2549 during which signals are not to be driven until devices sharing the interface have had time to power up.
 2550 To facilitate system implementation, the start of this interval shall be synchronized by an external signal
 2551 across devices.

2552 **10.2.7.1 Power-up control mechanisms**

2553 The device that provides the interface shall provide one or more of the following mechanisms to enable
2554 the system integrator to synchronize interface power-up among devices on the interface:

2555

- **Device power supply pin**

2556 The device has a power supply pin that the system integrator can use to control power-up of the
2557 interface. The device shall hold its outputs in a high-impedance state (current $< I_z$) for at least
2558 T_{pwrz} seconds after the power supply has initially reached its operating level (where the power
2559 supply operating level is specified by the device manufacturer).

2560

- **Device reset pin or other similar signal**

2561 The device has a reset pin or other signal that the system integrator can use to control the
2562 power-up of the interface. This signal shall be able to be driven asserted during interface power-
2563 up and de-asserted afterward. The device shall hold its outputs in a high-impedance state
2564 (current $< I_z$) for at least T_{pwrz} seconds after the signal has been de-asserted, other than as
2565 described in 10.2.7.2. It is highly recommended that a single signal be used; however, an
2566 implementation is allowed to use a combination of signals if required. Logic levels for the signals
2567 are as specified by the device manufacturer.

2568

- **REF_CLK detection**

2569 The device can elect to detect the presence of an active REF_CLK and use that for determining
2570 whether NC-SI power up has occurred. It is recommended that the device should count at least
2571 100 clocks and continue to hold its outputs in a high-impedance state (current $< I_z$) for at least
2572 T_{pwrz} seconds more (Informational: 100 clocks at 50 MHz is 2 us).

2573 **10.2.7.2 Power-up transients**

2574 It is possible that a device may briefly drive its outputs while the interface or device is first receiving
2575 power, due to ramping of the power supply and design of its I/O buffers. It is recommended that devices
2576 be designed so that such transients, if present, are less than V_{pwrt} and last for no more than T_{pwrt} .

2577 **10.2.8 REF_CLK startup**

2578 REF_CLK shall start up, run, and meet all associated AC and DC specifications within $T_{clkstrt}$ seconds of
2579 interface power up.

ANNEX A (normative)

Extending the Model

2580
2581
2582
2583

2584 This annex explains how the model can be extended to include vendor-specific content.

2585 **Commands extension**

2586 A Network Controller vendor can implement extensions and expose them using the OEM command, as
2587 described in 8.4.57.

2588 **Design considerations**

2589 This clause describes certain design considerations for vendors of Management Controllers.

2590 **PHY support**

2591 Although not a requirement of this specification, a Management Controller vendor can design the RBT
2592 interface in such a manner that it could also be configured for use with a conventional RMII PHY. This
2593 would enable the vendor's controller to also be used in applications where a direct, non-shared network
2594 connection is available or preferred for manageability.

2595 **Multiple Management Controllers support**

2596 Currently, there is no requirement for Management Controllers to be able to put their TXD output lines
2597 and other output lines into a high-impedance state, because the present definition assumes only one
2598 Management Controller on the bus. However, component vendors can provide such control capabilities in
2599 their devices to support possible future system topologies where more than one Management Controller
2600 shares the bus to enable functions such as Management Controller fail-over or to enable topologies
2601 where more than one Management Controller can participate in NC-SI communications on the bus. If a
2602 vendor elects to make such provision, it is recommended that the TXD line and the remaining output lines
2603 be independently and dynamically switched between a high-impedance state and re-enabled under
2604 firmware control.

2605

ANNEX B (informative)

Relationship to RMI Specification

2606
2607
2608
2609

2610 Differences with the *RMI Specification*

2611 The following list presents key differences and clarifications between the *NC-SI Specification* and
2612 sections in the [RMI Specification](#). (Section numbers refer to the [RMI Specification](#).)

- 2613 • General: Where specifications from [IEEE 802.3](#) apply, this specification uses the version
2614 specified in clause 2, rather than the earlier IEEE 802.3u version that is referenced by [RMI](#).
- 2615 • Section 1.0:
 - 2616 – The *NC-SI Specification* requires 100 Mbps support, but it does not specify a required
2617 minimum. (10 Mbps support is not required by NC-SI.)
 - 2618 – Item 4. (Signals may or may not be considered to be TTL. NC-SI is not 5-V tolerant.)
- 2619 • Section 2.0:
 - 2620 – Comment: NC-SI chip-to-chip includes considerations for multi-drop and allows for non-
2621 PCB implementations and connectors (that is, not strictly point-to-point).
- 2622 • Section 3.0:
 - 2623 – Note/Advisory: The NC-SI clock is provided externally. An implementation can have
2624 REF_CLK provided by one of the devices on the bus or by a separate device.
- 2625 • Section 5.0:
 - 2626 – For NC-SI, the term *PHY* is replaced by *Network Controller*.
- 2627 • Table 1:
 - 2628 – The information in Table 1 in the [RMI Specification](#) is superseded by tables in this
2629 specification.
- 2630 • Section 5.1, paragraph 2:
 - 2631 – The *NC-SI Specification* allows 100 ppm. This supersedes the [RMI Specification](#), which
2632 allows 50 ppm.
- 2633 • Section 5.1, paragraph 3:
 - 2634 – The NC-SI inherits the same requirements. The NC-SI MTU is required only to support
2635 Ethernet MTU with VLAN, as defined in the [IEEE 802.3](#) version listed in clause 2.
- 2636 • Section 5.1 paragraph 4:
 - 2637 – The [RMI Specification](#) states: "During a false carrier event, CRS_DV shall remain asserted
2638 for the duration of carrier activity." This statement is not applicable to full-duplex operation
2639 of the NC-SI. CRS_DV from the Network Controller is used only as a data valid (DV)
2640 signal. Because the Carrier Sense aspect of CRS_DV is not used for full-duplex operation
2641 of the NC-SI, the Network Controller would not generate false carrier events for the NC-SI.
2642 However, it is recommended that the MAC in the Management Controller be able to
2643 correctly detect and handle these patterns if they occur, as this would be part of enabling
2644 the Management Controller MAC to also be able to work with an RMI PHY.

- 2645 • Section 5.2:
 - 2646 – The NC-SI does not specify a 10 Mbps mode. The Carrier Sense aspect of CRS_DV is not
 - 2647 used for full-duplex operation of NC-SI.
- 2648 • Section 5.3.1:
 - 2649 – While the NC-SI does not specify Carrier Sense usage of CRS_DV, it is recommended that
 - 2650 a Management Controller allow for CRS_DV toggling, in which CRS_DV toggles at 1/2
 - 2651 clock frequency, and that Management Controller MACs tolerate this and realign bit
 - 2652 boundaries correctly in order to be able to work with an RMII PHY also.
- 2653 • Section 5.3.2:
 - 2654 – There is no 10 Mbps mode specified for the NC-SI RBT interface.
- 2655 • Section 5.3.3:
 - 2656 – Generally there is no expectation that the Network Controller will generate these error
 - 2657 conditions for the NC-SI RBT interface; however, the MAC in the Management Controller
 - 2658 should be able to correctly detect and handle these patterns if they occur.
- 2659 • Section 5.3.3:
 - 2660 – The NC-SI does not specify or require support for RMII Registers.
- 2661 • Section 5.5.2:
 - 2662 – Ignore (N/A) text regarding 10 Mbps mode. RBT does not specify or require interface
 - 2663 operation in 10 Mbps mode.
- 2664 • Section 5.6:
 - 2665 – The Network Controller will not generate collision patterns for the specified full-duplex
 - 2666 operation of the NC-SI; however, the MAC in the Management Controller should be able to
 - 2667 detect and handle these patterns if they occur in order to be able to work with an RMII PHY
 - 2668 also.
- 2669 • Section 5.7:
 - 2670 – NC-SI RBT uses the [IEEE 802.3](#) version listed in clause 2 instead of 802.3u as a
 - 2671 reference.
- 2672 • Section 5.8:
 - 2673 – Loopback operation is not specified for the NC-SI RBT interface.
- 2674 • Section 7.0:
 - 2675 – The NC-SI RBT electrical specifications (clause 10) take precedence. (For example,
 - 2676 section 7.4.1 in the [RMII Specification](#) for capacitance is superseded by *NC-SI*
 - 2677 *Specification* 25 pF and 50 pF target specifications.)
- 2678 • Section 8.0:
 - 2679 – NC-SI RBT uses the [IEEE 802.3](#) version listed in clause 2 as a reference, instead of
 - 2680 802.3u.

**ANNEX C
(informative)****Change log**

Version	Date	Description
1.0.0	2009-07-21	
1.0.1	2013-01-24	DMTF Standard release
1.1.0	2015-09-23	DMTF Standard release
1.1.1	2021-05-24	Updated to comply with ISO guidelines
