Version: 1.2.0WIP95

# Network Controller Sideband Interface (NC-SI) Specification

## Information for Work-in-Progress version:

**IMPORTANT:** This document is not a standard. It does not necessarily reflect the views of the DMTF or its members. Because this document is a Work in Progress, this document may still change, perhaps profoundly and without notice. This document is available for public review and comment until superseded.

**Provide any comments through the DMTF Feedback Portal:**

<https://www.dmtf.org/standards/feedback>

**Supersedes: 1.2WIP90**

**Document Class: Normative**

**Document Status: DMTF Work-in-Progress**

**Document Language: en-US**

## Copyright Notice

Copyright © 2009, 2013, 2015, 2019, 2021, 2022 DMTF. All rights reserved.

DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems management and interoperability. Members and non-members may reproduce DMTF specifications and documents, provided that correct attribution is given. As DMTF specifications may be revised from time to time, the particular version and release date should always be noted.

Implementation of certain elements of this standard or proposed standard may be subject to third-party patent rights, including provisional patent rights (herein "patent rights"). DMTF makes no representations to users of the standard as to the existence of such rights, and is not responsible to recognize, disclose, or identify any or all such third-party patent right, owners or claimants, nor for any incomplete or inaccurate identification or disclosure of such rights, owners or claimants. DMTF shall have no liability to any party, in any manner or circumstance, under any legal theory whatsoever, for failure to recognize, disclose, or identify any such third-party patent rights, or for such party's reliance on the standard or incorporation thereof in its product, protocols or testing procedures. DMTF shall have no liability to any party implementing such standard, whether such implementation is foreseeable or not, nor to any patent owner or claimant, and shall have no liability or responsibility for costs or losses incurred if a standard is withdrawn or modified after publication, and shall be indemnified and held harmless by any party implementing the standard from any and all claims of infringement by a patent owner for such implementations.

For information about patents held by third-parties which have notified the DMTF that, in their opinion, such patent may relate to or impact implementations of DMTF standards, visit <https://www.dmtf.org/about/policies/disclosures.php>.

## CONTENTS

35	Foreword .....	15
36	Introduction.....	16
37	1 Scope .....	17
38	2 Normative references .....	17
39	3 Terms and definitions .....	18
40	3.1 Wording Interpretation .....	18
41	3.2 Requirement term definitions .....	18
42	3.3 NC-SI term definitions.....	20
43	3.4 Numbers and number bases .....	23
44	3.5 Network Addresses .....	23
45	3.6 Reserved fields .....	23
46	4 Acronyms and abbreviations.....	23
47	5 NC-SI overview .....	26
48	5.1 General .....	26
49	5.2 Defined topologies .....	27
50	5.3 Single and integrated Network Controller implementations.....	28
51	5.4 Transport stack .....	30
52	5.5 Transport protocol.....	31
53	5.6 Byte and bit ordering for transmission .....	31
54	6 Operational behaviors .....	32
55	6.1 Typical operational model.....	32
56	6.1.1 State definitions and defined states.....	32
57	6.1.2 NC-SI RBT pre-operational states .....	33
58	6.1.3 Package Ready state.....	33
59	6.1.4 Initial State .....	34
60	6.1.5 NC-SI Initial State recovery .....	35
61	6.1.6 State transition diagram .....	35
62	6.1.7 State diagram for NC-SI operation with hardware arbitration.....	37
63	6.1.8 Resets .....	38
64	6.1.9 Network Controller Channel ID .....	38
65	6.1.10 Configuration-related settings.....	39
66	6.1.11 Transmitting Pass-through packets from the Management Controller .....	40
67	6.1.12 Receiving Pass-through packets for the Management Controller .....	40
68	6.1.13 Pass-through operation in multiple medium implementations .....	41
69	6.1.14 Startup sequence examples .....	41
70	6.2 NC-SI traffic types.....	46
71	6.2.1 Overview .....	46
72	6.2.2 Command protocol.....	46
73	6.3 Link configuration and control .....	49
74	6.3.1 Link Configuration .....	49
75	6.3.2 Link Status .....	49
76	6.4 Frame filtering for Pass-through mode .....	49
77	6.4.1 Overview .....	49
78	6.4.2 Multicast filtering .....	49
79	6.4.3 Broadcast filtering .....	49
80	6.4.4 VLAN filtering .....	49
81	6.5 Output buffering behavior .....	51
82	6.6 NC-SI flow control .....	51
83	6.7 Asynchronous Event Notification .....	51
84	6.8 AEN handling in multiple medium implementations .....	52
85	6.9 Error handling .....	52

86	6.9.1	Overview .....	52
87	6.9.2	Transport errors .....	52
88	6.9.3	Missing responses .....	53
89	6.9.4	Detecting Pass-through traffic interruption .....	53
90	6.10	Support for additional network fabrics .....	54
91	6.10.1	FC support .....	54
92	6.11	PLDM and SPDM transport .....	54
93	7	Arbitration in configurations with multiple Network Controller packages .....	57
94	7.1	Overview .....	57
95	7.2	Multi-controller RBT .....	57
96	7.3	Hardware arbitration .....	58
97	7.3.1	General .....	58
98	7.3.2	Hardware arbitration opcodes.....	59
99	7.3.3	Opcode operations.....	61
100	7.3.4	Bypass mode .....	63
101	7.3.5	Hardware arbitration startup .....	63
102	7.3.6	ARB_MSTR assignment.....	63
103	7.3.7	Token timeout mechanism.....	63
104	7.3.8	Timing considerations.....	64
105	7.3.9	Example hardware arbitration state machine .....	65
106	7.4	Command-based arbitration .....	67
107	8	Packet definitions .....	68
108	8.1	NC-SI packet encapsulation .....	68
109	8.1.1	Ethernet frame header .....	68
110	8.1.2	Frame Check Sequence .....	69
111	8.1.3	Data length.....	69
112	8.2	Control Packet data structure .....	69
113	8.2.1	Control Packet header .....	69
114	8.2.2	Control Packet payload.....	71
115	8.2.3	Command packet payload .....	72
116	8.2.4	Response packet payload .....	72
117	8.2.5	Response codes and reason codes .....	73
118	8.2.6	AEN packet format.....	75
119	8.2.7	Single OEM AEN packet format .....	76
120	8.2.8	Multiple OEMs AEN packet format .....	76
121	8.3	Control Packet type definitions .....	77
122	8.4	Transport-specific Control Packet type definitions .....	82
123	8.5	Command and response packet formats.....	82
124	8.5.1	NC-SI command frame format.....	82
125	8.5.2	NC-SI response packet format .....	83
126	8.5.3	Clear Initial State command (0x00).....	84
127	8.5.4	Clear Initial State response ( 0x80 ) .....	84
128	8.5.5	Select Package command (0x01).....	85
129	8.5.6	Select Package response ( 0x81 ) .....	86
130	8.5.7	Deselect Package command (0x02).....	86
131	8.5.8	Deselect Package response (0x82).....	87
132	8.5.9	Enable Channel command (0x03) .....	88
133	8.5.10	Enable Channel response (0x83) .....	88
134	8.5.11	Disable Channel command (0x04) .....	88
135	8.5.12	Disable Channel response (0x84) .....	89
136	8.5.13	Reset Channel command (0x05) .....	89
137	8.5.14	Reset Channel response (0x85) .....	89
138	8.5.15	Enable Channel Network TX command (0x06) .....	90
139	8.5.16	Enable Channel Network TX response (0x86) .....	90

140	8.5.17	Disable Channel Network TX command (0x07).....	90
141	8.5.18	Disable Channel Network TX response (0x87).....	91
142	8.5.19	AEN Enable command (0x08) .....	91
143	8.5.20	AEN Enable response ( 0x88 ) .....	92
144	8.5.21	Set Link command (0x09) .....	93
145	8.5.22	Set Link Response (0x89).....	96
146	8.5.23	Get Link Status command (0x0A) .....	97
147	8.5.24	Get Link Status response (0x8A) .....	97
148	8.5.25	Set VLAN Filter command (0x0B) .....	102
149	8.5.26	Set VLAN Filter response (0x8B) .....	104
150	8.5.27	Enable VLAN command (0x0C) .....	104
151	8.5.28	Enable VLAN response (0x8C) .....	105
152	8.5.29	Disable VLAN command (0x0D).....	105
153	8.5.30	Disable VLAN response (0x8D).....	106
154	8.5.31	Set MAC Address command (0x0E) .....	106
155	8.5.32	Set MAC Address response (0x8E) .....	108
156	8.5.33	Enable Broadcast Filter command (0x10) .....	108
157	8.5.34	Enable Broadcast Filter response (0x90) .....	110
158	8.5.35	Disable Broadcast Filter command (0x11).....	111
159	8.5.36	Disable Broadcast Filter response (0x91).....	111
160	8.5.37	Enable Global Multicast Filter command (0x12).....	111
161	8.5.38	Enable Global Multicast Filter response (0x92).....	116
162	8.5.39	Disable Global Multicast Filter command (0x13) .....	116
163	8.5.40	Disable Global Multicast Filter response (0x93) .....	116
164	8.5.41	Set NC-SI Flow Control command (0x14) .....	117
165	8.5.42	Set NC-SI Flow Control response (0x94) .....	118
166	8.5.43	Get Version ID command (0x15) .....	118
167	8.5.44	Get Version ID Response (0x95).....	118
168	8.5.45	Get Capabilities command (0x16) .....	121
169	8.5.46	Get Capabilities response (0x96).....	121
170	8.5.47	Get Parameters command (0x17).....	124
171	8.5.48	Get Parameters response (0x97).....	124
172	8.5.49	Get Controller Packet Statistics command (0x18).....	127
173	8.5.50	Get Controller Packet Statistics response (0x98).....	127
174	8.5.51	Get NC-SI Statistics command (0x19).....	131
175	8.5.52	Get NC-SI Statistics response (0x99).....	132
176	8.5.53	Get NC-SI Pass-through Statistics command (0x1A) .....	133
177	8.5.54	Get NC-SI Pass-through Statistics response (0x9A) .....	134
178	8.5.55	Get Package Status command (0x1B).....	135
179	8.5.56	Get Package Status response (0x9B).....	136
180	8.5.57	Get NC Capabilities and Settings command (0x25) .....	136
181	8.5.58	Get NC Capabilities and Settings response (0xA5) .....	137
182	8.5.59	Set NC Configuration command (0x26).....	139
183	8.5.60	Set NC Configuration response ( 0xA6 ) .....	140
184	8.5.61	Get PF Assignment command ( 0x27 ) .....	140
185	8.5.62	Get PF Assignment Response ( 0xA7 ) .....	140
186	8.5.63	Set PF Assignment command ( 0x28 ) .....	143
187	8.5.64	Set PF Assignment Response ( 0xA8 ) .....	145
188	8.5.65	Get VF Allocation command ( 0x35 ) .....	145
189	8.5.66	Get VF Allocation Response ( 0xB5 ) .....	146
190	8.5.67	Set VF Allocation command ( 0x36 ) .....	146
191	8.5.68	Set VF Allocation Response ( 0xA8 ) .....	147

192	8.5.69	Get Channel Configuration command (0x29) .....	147
193	8.5.70	Get Channel Configuration response (0xA9) .....	148
194	8.5.71	Set Channel Configuration command (0x2A) .....	149
195	8.5.72	Set Channel Configuration response (0xAA) .....	151
196	8.5.73	Get Partition Configuration command (0x2B) .....	151
197	8.5.74	Get Partition Configuration response (0xAB) .....	151
198	8.5.75	Set Partition Configuration command (0x2C) .....	156
199	8.5.76	Set Partition Configuration response (0xAC) .....	158
200	8.5.77	Get Boot Config Command (0x2D) .....	158
201	8.5.78	Get Boot Config Response (0xAD) .....	159
202	8.5.79	Set Boot Config command (0x2E) .....	164
203	8.5.80	Set Boot Config Response (0xAE) .....	165
204	8.5.81	Get Partition Statistics command (0x2F) .....	166
205	8.5.82	Get Partition Statistics response for Ethernet (0xAF) .....	167
206	8.5.83	Get Partition Statistics response for FCoE (0xAF) .....	169
207	8.5.84	Get Partition Statistics response for iSCSI (0xAF) .....	171
208	8.5.85	Get Partition Statistics response for InfiniBand (0xAF) .....	172
209	8.5.86	Get Partition Statistics response for RDMA (0xAF) .....	174
210	8.5.87	Get Partition Statistics Response for Fibre Channel (0xAF) .....	176
211	8.5.88	Get FC Link Status command (0x31) .....	178
212	8.5.89	Get FC Link Status Response (0xB1) .....	179
213	8.5.90	Get Transceiver Management Data command (0x32) .....	181
214	8.5.91	Get Transceiver Management Data response (0xB2) .....	182
215	8.5.92	Get InfiniBand Link Status command (0x38) .....	184
216	8.5.93	Get InfiniBand Link Status Response (0xB8) .....	184
217	8.5.94	Get IB Statistics command (0x39) .....	186
218	8.5.95	Get IB Statistics Response (0xB9) .....	187
219	8.5.96	Settings Commit command (0x47) .....	188
220	8.5.97	Settings Commit response (0xC7) .....	189
221	8.5.98	Get ASIC Temperature (0x48) .....	189
222	8.5.99	Get ASIC Temperature Response (0xC8) .....	190
223	8.5.100	Get Ambient Temperature (0x49) .....	190
224	8.5.101	Get Ambient Temperature Response (0xC9) .....	191
225	8.5.102	Get Transceiver Temperature (0x4A) .....	191
226	8.5.103	Get Transceiver Temperature Response (0xCA) .....	192
227	8.5.104	Thermal Shutdown Control Command (0x4B) .....	192
228	8.5.105	Thermal Shutdown Control Response (0xCB) .....	193
229	8.5.106	Get Inventory Information command (0x4E) .....	194
230	8.5.107	Get Inventory Information response (0xCE) .....	195
231	8.5.108	Set Pass-through Mode Control Command (0x33) .....	196
232	8.5.109	Set Pass-through Mode Control Response (0xB3) .....	197
233	8.5.110	Get Pass-through Mode Command (0x34) .....	197
234	8.5.111	Get Pass-through Mode Response (0xB4) .....	197
235	8.5.112	Transmit Data to NC command (0x4C) .....	198
236	8.5.113	Transmit Data to NC response (0xCC) .....	200
237	8.5.114	Receive Data from NC command (0x4D) .....	200
238	8.5.115	Receive Data from NC response (0xCD) .....	202
239	8.5.116	SPDM command (0x60) .....	203
240	8.5.117	SPDM Response (0xE0) .....	203
241	8.5.118	Query Pending NC SPDM Request (0x61) .....	204
242	8.5.119	Query Pending NC SPDM Request Response (0xE1) .....	204

243	8.5.120 Send NC SPDM Reply (0x62).....	205
244	8.5.121 Send NC SPDM Reply Response (0xE2) .....	205
245	8.5.122 Query and Set OEM AEN command ( 0x54 ) .....	206
246	8.5.123 Query and Set OEM AEN Response (0xD4).....	207
247	8.5.124 OEM command ( 0x50 ) .....	208
248	8.5.125 OEM response ( 0xD0 ) .....	208
249	8.5.126 PLDM Request (0x51) .....	209
250	8.5.127 PLDM Response ( 0xD1 ) .....	209
251	8.5.128 Query Pending NC PLDM Request (0x56) .....	210
252	8.5.129 Query Pending NC PLDM Request Response (0xD6).....	210
253	8.5.130 Send NC PLDM Reply (0x57).....	211
254	8.5.131 Send NC PLDM Reply Response (0xD7).....	211
255	8.5.132 Transport-specific AEN Enable command (0x55).....	212
256	8.5.133 Transport-specific AENs Enable Response (0xD5) .....	212
257	8.5.134 Get MC MAC Address command (0x58) .....	213
258	8.5.135 Get MC MAC Address response (0xD8) .....	213
259	8.5.136 Get Package UUID command (0x52) .....	214
260	8.5.137 Get Package UUID response (0xD2) .....	214
261	8.6 AEN packet formats .....	215
262	8.6.1 Link Status Change AEN .....	216
263	8.6.2 Configuration Required AEN .....	216
264	8.6.3 Host Network Controller Driver Status Change AEN.....	216
265	8.6.4 Delayed Response Ready AEN.....	217
266	8.6.5 InfiniBand Link Status Change AEN .....	217
267	8.6.6 Fibre Channel Link Status Change AEN .....	218
268	8.6.7 Transceiver Event AEN .....	218
269	8.6.8 Request Data Transfer AEN .....	220
270	8.6.9 Partition Link Status Change AEN.....	221
271	8.6.10 Thermal Shutdown Event AEN .....	222
272	8.6.11 Pending PLDM Request AEN.....	222
273	8.6.12 Pending SPDM Request AEN .....	223
274	9 Packet-based and opcode timing .....	224
275	10 RBT Electrical specification .....	226
276	10.1 Topologies .....	226
277	10.2 Electrical and signal characteristics and requirements.....	227
278	10.2.1 Companion specifications.....	227
279	10.2.2 Full-duplex operation .....	227
280	10.2.3 Signals .....	227
281	10.2.4 High-impedance control .....	228
282	10.2.5 Hardware Implementations.....	228
283	10.2.6 DC characteristics.....	229
284	10.2.7 AC characteristics .....	230
285	10.2.8 Interface power-up.....	233
286	10.2.9 REF_CLK startup.....	234
287	10.3 RBT Implementation guidance .....	234
288	ANNEX A (normative) Extending the model .....	235
289	ANNEX B (informative) Relationship to RMI Specification .....	236
290	ANNEX C (informative) Change log.....	238
291	Bibliography .....	239
292		

## 293 Figures

294	Figure 1 – NC-SI functional block diagram .....	26
295	Figure 2 – NC-SI RBT traffic flow diagram.....	27
296	Figure 3 – Example topologies supported by the NC-SI.....	28
297	Figure 4 – Network Controller integration options.....	29
298	Figure 5 – NC-SI transport stack .....	31
299	Figure 6 – NC-SI package/channel operational state diagram .....	36
300	Figure 7 – NC-SI operational state diagram for hardware arbitration operation .....	37
301	Figure 8 – MC steps when the MC does not have prior knowledge of hardware arbitration.....	45
302	Figure 9 – NC-SI packet filtering flowchart .....	50
303	Figure 10 – Basic multi-drop block diagram.....	57
304	Figure 11 – Multiple Network Controllers in a ring format.....	59
305	Figure 12 – Opcode to RXD relationship .....	60
306	Figure 13 – Example TOKEN to transmit relationship .....	64
307	Figure 14 – Hardware arbitration state machine.....	65
308	Figure 15 – Ethernet frame encapsulation of NC-SI packet data without VLAN tag .....	68
309	Figure 16 – Example NC-SI RBT signal interconnect topology .....	226
310	Figure 17 – DC measurements .....	229
311	Figure 18 – AC measurements .....	231
312	Figure 19 – Overshoot measurement .....	232
313	Figure 20 – Undershoot measurement .....	233
314		

## 315 Tables

316	Table 1 – NC-SI operating state descriptions .....	32
317	Table 2 – Channel ID format .....	39
318	Table 3 – Channel Ready state configuration settings .....	40
319	Table 4 – Commands for RBT binding.....	54
320	Table 5 – Hardware arbitration di-bit encoding .....	59
321	Table 6 – Hardware arbitration opcode format .....	60
322	Table 7 – Hardware arbitration states.....	66
323	Table 8 – Hardware arbitration events.....	67
324	Table 9 – Ethernet Header Format .....	68
325	Table 10 – Control Packet header format .....	69
326	Table 11 – Generic example of Control Packet payload .....	71
327	Table 12 – Generic example of Response packet payload format .....	72
328	Table 13 – Generic example of Delayed Response packet payload .....	73
329	Table 14 – Reason code ranges .....	73
330	Table 15 – Standard response code values .....	74
331	Table 16 – Standard Reason Code Values .....	75
332	Table 17 – AEN packet format.....	76
333	Table 18 – AEN Type Ranges .....	76
334	Table 19 – OEM AEN packet format.....	76
335	Table 20 – Multiple OEMs AEN packet format .....	77

336	Table 21 – Command and Response types.....	77
337	Table 22 – Transport-specific Command and Response types.....	82
338	Table 23 – Example of complete minimum-sized NC-SI command packet.....	83
339	Table 24 – Example of complete minimum-sized NC-SI response packet.....	83
340	Table 25 – Clear Initial State command packet format.....	84
341	Table 26 – Clear Initial State response packet format.....	84
342	Table 27 – Select Package command packet format .....	86
343	Table 28 – Features Control byte .....	86
344	Table 29 – Select package response packet format.....	86
345	Table 30 – Deselect Package command packet format .....	87
346	Table 31 – Deselect Package response packet format .....	87
347	Table 32 – Enable Channel command packet format.....	88
348	Table 33 – Enable Channel response packet format.....	88
349	Table 34 – Disable Channel command packet format.....	89
350	Table 35 – Disable Channel response packet format.....	89

## Foreword

596 The *Network Controller Sideband Interface (NC-SI) Specification* (DSP0222) was prepared by the PMCI  
597 Working Group.

598 This version supersedes version 1.2WIP90. For a list of changes, see the Change Log in ANNEX C.

599 DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems  
600 management and interoperability.

## Introduction

619 In out-of-band management environments, the interface between the out-of-band Management Controller  
620 and the Network Controller is critical. This interface is responsible for supporting communication between  
621 the Management Controller and external management applications.

622 The goal of this specification is to define an interoperable sideband communication interface standard to  
623 enable the exchange of management data between the Management Controller and Network Controller.  
624 The Sideband Interface is intended to provide network access for the Management Controller, and the  
625 Management Controller is expected to perform all the required network functions.

626 This specification defines the protocol and commands necessary for the operation of the sideband  
627 communication interface. This specification also defines physical and electrical characteristics of a  
628 sideband binding interface that is a variant of RMII targeted specifically for sideband communication  
629 traffic.

630 The specification is primarily intended for architects and engineers involved in the development of  
631 Network and Management Controllers that will be used in providing out-of-band management  
632 functionality.  
633

# Network Controller Sideband Interface (NC-SI) Specification

## 1 Scope

This specification defines the functionality and behavior of the Sideband Interface responsible for connecting the Network Controller (including Ethernet, Fibre Channel, and InfiniBand controllers) to the Management Controller. It also outlines the behavioral model of the (Ethernet) network traffic destined for the Management Controller from the Network Controller.

This specification defines the following two aspects of the Network Controller Sideband Interface (NC-SI):

- behavior of the interface, which include its operational states as well as the states of the associated components
- the payloads and commands of the communication protocol supported over the interface

The scope of this specification is limited to addressing only a single Management Controller communicating with one or more Network Controllers.

This specification also defines the following aspects of a 3.3V RMI-Based Transport (RBT) based physical medium:

- transport binding for NC-SI over RBT
- electrical and timing requirements for the RBT
- an optional hardware arbitration mechanism for RBT

Only the topics that may affect the behavior of the Network Controller or Management Controller, as it pertains to the Sideband Interface operations, are discussed in this specification.

## 689 3 Terms and definitions

### 690 3.1 Wording Interpretation

- 691 In this document, some terms have a specific meaning beyond the normal English meaning. Those terms  
692 are defined in this clause.
- 693 The terms "shall" ("required"), "shall not", "should" ("recommended"), "should not" ("not recommended"),  
694 "may", "need not" ("not required"), and "can" in this document are to be interpreted as described in  
695 [ISO/IEC Directives, Part 2](#), Clause 7. The terms in parentheses are alternatives for the preceding term,  
696 for use in exceptional cases when the preceding term cannot be used for linguistic reasons. Note that  
697 [ISO/IEC Directives, Part 2](#), Clause 7 specifies additional alternatives. Occurrences of such additional  
698 alternatives shall be interpreted in their normal English meaning.
- 699 The terms "clause", "subclause", "paragraph", and "annex" in this document are to be interpreted as  
700 described in [ISO/IEC Directives, Part 2](#), Clause 6.
- 701 The terms "normative" and "informative" in this document are to be interpreted as described in [ISO/IEC](#)  
702 [Directives, Part 2](#), Clause 3. In this document, clauses, subclauses, or annexes labeled "(informative)" do  
703 not contain normative content. Notes and examples are always informative elements.
- 704 The terms defined in [DSP0004](#), [DSP0223](#), and [DSP1001](#) apply to this document. The following additional  
705 terms are used in this document.

### 706 3.2 Requirement term definitions

- 707 This clause defines key phrases and words that denote requirement levels in this specification.

708	<b>3.2.1</b>
709	<b>can</b>
710	indicates an ability or capability expressed by the specification or of the possibility of some outcome in the
711	context of the specification
712	<b>3.2.2</b>
713	<b>cannot</b>
714	indicates the inability or denial of the possibility of a certain outcome in the context of the specification
715	<b>3.2.3</b>
716	<b>conditional</b>
717	indicates that an item is required under specified conditions
718	<b>3.2.4</b>
719	<b>deprecated</b>
720	indicates that an element or profile behavior has been outdated by newer constructs
721	<b>3.2.5</b>
722	<b>mandatory</b>
723	indicates that an item is required under all conditions
724	<b>3.2.6</b>
725	<b>may</b>
726	a permission expressed by this specification
727	<b>3.2.7</b>
728	<b>may not</b>
729	an expression of permission in the negative; a lack of requirement
730	<b>3.2.8</b>
731	<b>not recommended</b>
732	indicates that valid reasons may exist in particular circumstances when the particular behavior is
733	acceptable or even useful, but the full implications should be understood and carefully weighed before
734	implementing any behavior described with this label
735	<b>3.2.9</b>
736	<b>obsolete</b>
737	indicates that an item was defined in prior specifications but has been removed from this specification
738	<b>3.2.10</b>
739	<b>optional</b>
740	indicates that an item is not mandatory, conditional, or prohibited
741	<b>3.2.11</b>
742	<b>recommended</b>
743	indicates that valid reasons may exist in particular circumstances to ignore a particular item, but the full
744	implications should be understood and carefully weighed before choosing a different course
745	<b>3.2.12</b>
746	<b>required</b>
747	indicates that the item is an absolute requirement of the specification

**3.2.13****shall**

indicates that the item is an absolute requirement of the specification

**3.2.14****shall not**

indicates that the item is an absolute prohibition of the specification

**3.2.15****should**

indicates a recommendation of the specification, but the full implications should be understood and carefully weighed before choosing a different course

**3.2.16****should not**

indicates a recommendation against, but the full implications should be understood and carefully weighed before implementing any behavior described with this label

**3.3 NC-SI term definitions**

For the purposes of this document, the following terms and definitions apply.

**3.3.1****frame**

a data packet of fixed or variable length that has been encoded for digital transmission over a node-to-node link

*Frame* is used in references to [IEEE 802.3 Frames](#). *Packet* is used in all other references.

**3.3.2****packet**

a formatted block of information carried by a computer network

*Frame* is used in references to [IEEE 802.3 Frames](#). *Packet* is used in all other references.

**3.3.3****external network interface**

the interface of the Network Controller that provides connectivity to the external network infrastructure; also known as *port*

**3.3.4****internal host interface**

the interface of the Network Controller that provides connectivity to the host operating system running on the platform

**3.3.5****Management Controller**

an intelligent entity composed of hardware/firmware/software that resides within a platform and is responsible for some or all of the management functions associated with the platform; also known as BMC and Service Processor

- 786 **3.3.6**  
787 **Network Controller**  
788 the component within a system that is responsible for providing connectivity to an external Ethernet, Fibre  
789 Channel, or InfiniBand network
- 790 **3.3.7**  
791 **remote media**  
792 a manageability feature that enables remote media devices to appear as if they are attached locally to the  
793 host
- 794 **3.3.8**  
795 **Network Controller Sideband Interface**  
796 **NC-SI**  
797 The RBT interface of the Network Controller that provides network connectivity to a Management  
798 Controller; also shown as *Sideband Interface*, *RBT* or *NC-SI* as appropriate in the context
- 799 **3.3.9**  
800 **integrated controller**  
801 a Network Controller device that supports two or more channels for the NC-SI that share a common  
802 NC-SI physical interface (for example, a Network Controller that has two or more physical network ports  
803 and a single NC-SI bus connection)
- 804 **3.3.10**  
805 **multi-drop**  
806 refers to the situation in which multiple physical communication devices share an electrically common bus  
807 and a single device acts as the master of the bus and communicates with multiple “slave” or “target”  
808 devices
- 809 Related to NC-SI, a Management Controller serves the role of the master, and the Network Controllers  
810 are the target devices
- 811 **3.3.11**  
812 **point-to-point**  
813 refers to the situation in which only a single Management Controller and single Network Controller  
814 package are used on the bus in a master/slave relationship, where the Management Controller is the  
815 master
- 816 **3.3.12**  
817 **Channel**  
818 refers to the logical representation of a network port in a Network Controller that supports Control traffic  
819 and may support Pass-through traffic
- 820 A Network Controller may have a 1:1 relationship of NC-SI channels to physical network ports, or Network  
821 Controllers that support partitioning can have multiple channels on a given network port
- 822 **3.3.13**  
823 **Partition**  
824 one or more NC-SI channels in a Network Controller that share a common network port
- 825 **3.3.14**  
826 **Package**  
827 one or more NC-SI channels in a Network Controller that share a common set of electrical buffers and  
828 common electrical buffer controls for the NC-SI bus

829 Typically a single, logical NC-SI package exists for a single physical Network Controller package (chip or  
830 module). However, this specification allows a single physical chip or module to hold multiple NC-SI logical  
831 packages

832 **3.3.15**  
833 **control traffic**  
834 **Control Packets**  
835 **control packets**

836 command, response, and asynchronous event notification packets transmitted between the Management  
837 Controller and Network Controllers for the purpose of managing the NC and NC-SI

838 **3.3.16**  
839 **Command**

840 Control Packet sent by the Management Controller to the Network Controller to request the Network  
841 Controller to perform an action, and/or return data

842 **3.3.17**  
843 **Response**

844 Control Packet sent by the Network Controller to the Management Controller as a positive  
845 acknowledgement of a command received from the Management Controller, and to provide the execution  
846 outcome of the command, as well as to return any required data

847 **3.3.18**  
848 **Asynchronous Event Notification**

849 Control Packet sent by the Network Controller to the Management Controller as an explicit notification of  
850 the occurrence of an event of interest to the Management Controller

851 **3.3.19**  
852 **pass-through traffic**  
853 **pass-through packets**

854 network packets passed between the external network and the Management Controller through the  
855 Network Controller

856 **3.3.20**  
857 **RBT**  
858 **RMII-Based Transport**

859 Electrical and timing specification for a 3.3V-signaling physical medium that is derived from [RMII](#)

860 **3.3.21**  
861 **PCIe Endpoint**

862 Also PCI Port, physically the collection of Transmitters and Receivers located on the same chip that  
863 define a Link, logically the interface between a component and a PCI Express Link. For the purposes of  
864 this specification, it is a PCIe upstream port on the NC that is assigned a PCI Bus number when  
865 connecting to a PCIe Switch or Root Complex

866 **3.3.22**  
867 **PCIe Link**

868 The collection of two Ports and their interconnecting Lanes. A Link is a dual-simplex communications path  
869 between two components.

### 3.4 Numbers and number bases

Numbers in this specification are written as follows:

- Hexadecimal numbers are written with a “0x” prefix (for example, 0xFF and 0x80).
- Binary numbers are written with a lowercase “b” suffix (for example, 1001b and 10b).
- Hexadecimal and binary numbers are formatted in the Courier New font.
- “uint8” describes an unsigned 8-bit integer value.

### 3.5 Network Addresses

Network addresses in this specification are written as follows:

- IPv4 addresses are written as decimal numbers with period (.) separators
- IPv6 addresses are written as hexadecimal numbers with colon (:) separators
- MAC addresses are written as 6 hexadecimal number pairs with colon (:) separators
- InfiniBand GUIDs are written as hexadecimal numbers with no separators
- Fibre Channel WWNs are written as hexadecimal numbers with no separators

### 3.6 Reserved fields

Unless otherwise specified, reserved fields (bytes, bits, etc.) are reserved for future use and should be written as zeros and ignored when read.

## 4 Acronyms and abbreviations

The following symbols and abbreviations are used in this document.

#### 4.1

##### AC

alternating current

#### 4.2

##### AEN

Asynchronous Event Notification

#### 4.3

##### BMC

Baseboard Management Controller (often used interchangeably with MC)

#### 4.4

##### CMIS

Common Management Interface Specification

#### 4.5

##### CRC

cyclic redundancy check

#### 4.6

##### CRS\_DV

a physical NC-SI signal used to indicate Carrier Sense/Received Data Valid

906	<b>4.7</b>
907	<b>DC</b>
908	direct current
909	<b>4.8</b>
910	<b>DHCP</b>
911	Dynamic Host Configuration Protocol
912	<b>4.9</b>
913	<b>EEE</b>
914	Energy Efficient Ethernet
915	<b>4.10</b>
916	<b>FC</b>
917	<b>Fibre Channel</b>
918	<b>4.11</b>
919	<b>FCS</b>
920	Frame Check Sequence
921	<b>4.12</b>

931	<b>NC-SI</b>
932	Network Controller Sideband Interface
933	<b>4.16</b>
934	<b>NC-SI RX</b>
935	the direction of traffic on RBT from the Network Controller to the Management Controller
936	<b>4.17</b>
937	<b>NC-SI TX</b>
938	the direction of traffic RBT to the Network Controller from the Management Controller
939	<b>4.18</b>
940	<b>RMII</b>
941	Reduced Media Independent Interface
942	<b>4.19</b>
943	<b>RX</b>
944	Receive

945 **4.20**  
946 **RXD**  
947 physical NC-SI signals used to transmit data from the Network Controller to the Management Controller

948 **4.21**  
949 **RX\_ER**  
950 a physical NC-SI signal used to indicate a Receive Error

951 **4.22**  
952 **SerDes**  
953 serializer/deserializer; an integrated circuit (IC or chip) transceiver that converts parallel data to serial data  
954 and vice-versa. This is used to support interfaces such as 1000Base-X and others.

955 **4.23**  
956 **SFF**  
957 Small Form Factor

958 **4.24**  
959 **TX**  
960 Transmit

961 **4.25**  
962 **TXD**  
963 physical NC-SI signals used to transmit data from the Management Controller to the Network Controller

964 **4.26**  
965 **VLAN**  
966 Virtual LAN  
967

## 5 NC-SI overview

### 5.1 General

This specification enables a common interface definition between different Management Controller and Network Controller vendors. This specification addresses not only the electrical and protocol specifications, but also the system-level behaviors for the Network Controller and the Management Controller related to the NC-SI.

The NC-SI is defined as the interface (protocol, messages, and medium) between a Management Controller and one or more Network Controllers. This interface, referred to as a Sideband Interface in Figure 1, is responsible for providing external network connectivity for the Management Controller while also allowing the external network interface to be shared with traffic to and from the host.

The specification of how the NC-SI protocol and messages are implemented over a particular physical medium is referred to as a transport binding. This document, DSP0222, includes the definition of the transport binding, electrical, framing, and timing specifications for a physical interface called RBT (RMII-based Transport). Electrically, RBT, as described in clause 10, is similar to the Reduced Media Independent Interface™ (RMII) – see ANNEX B. Transport bindings for NC-SI over other media and transport protocols are defined through external transport binding specifications, such as [DSP0261](#), the *NC-SI over MCTP Transport Binding Specification*. That specification defines the Get Supported Media command (0x54) which is used to discover support for operations over multiple media types. This command may be issued on any NC-SI transport including RBT.

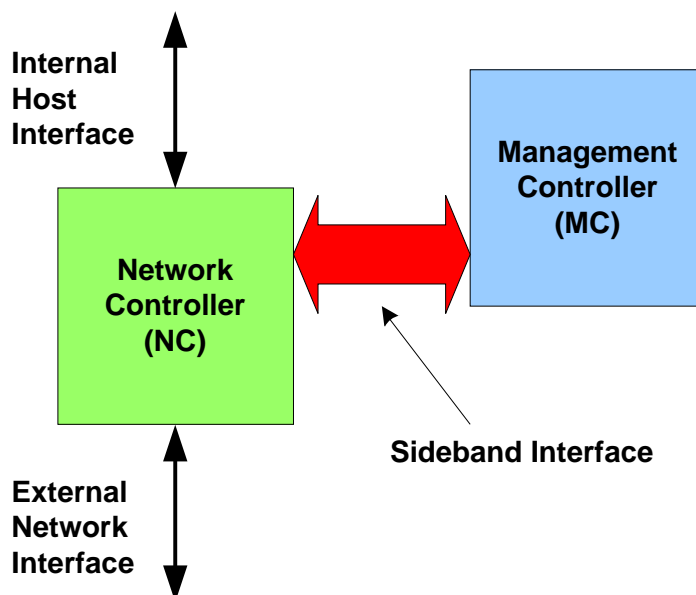

Figure 1 – NC-SI functional block diagram

NC-SI traffic flow is illustrated in Figure 2. Two classes of packet data can be delivered over the Sideband Interface:

- “Pass-through” packets that are transferred between the Management Controller and the external network and/or an internal host.
- “Control” packets that are transferred between the Management Controller and Network Controllers for control or configuration functionality. This specification defines NC-SI commands and responses as well as a mechanism to customize and extend functionality via OEM commands – see ANNEX A.

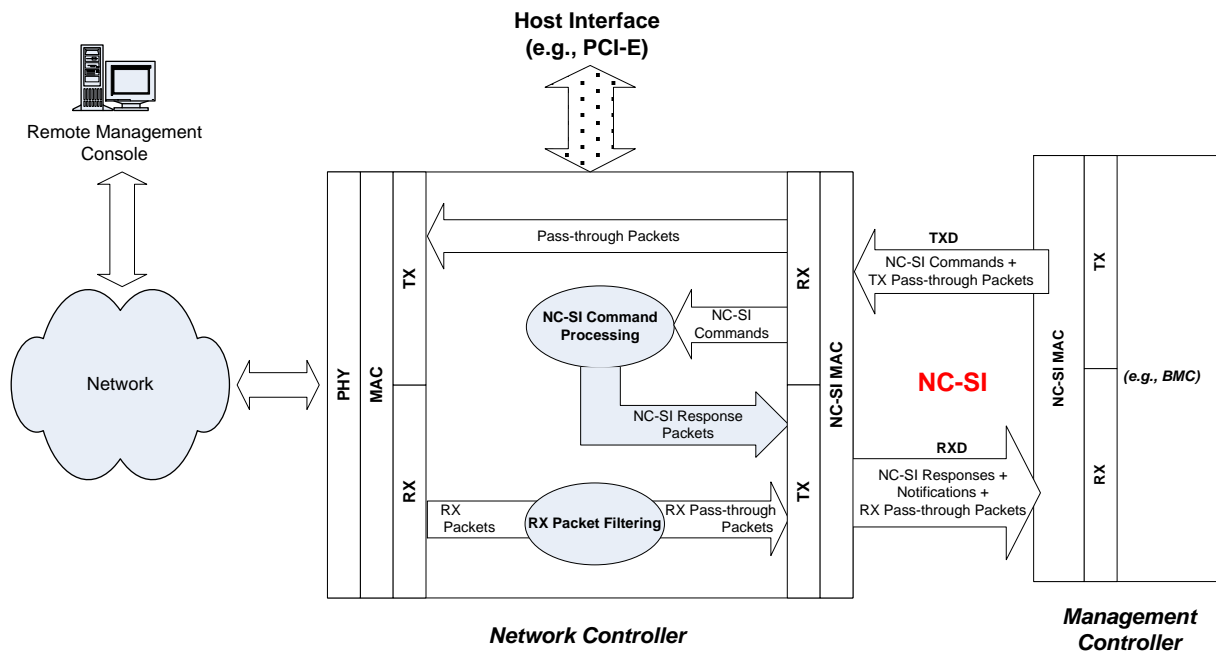

Figure 2 – NC-SI RBT traffic flow diagram

NC-SI is intended to operate independently from the in-band activities of the Network Controller. As such, the Sideband Interface is not specified to be visible through the host interface of the Network Controller. From the external world, this interface should behave and operate like a standard Ethernet Interface.

## 5.2 Defined topologies

The topologies supported under this specification apply to the case in which a single Management Controller is actively communicating with one or more Network Controllers on the Sideband Interface over RBT. The RBT electrical specification is targeted to directly support up to four physical Network Controller packages. The protocol specification allows up to eight Network Controller packages, with up to 31 channels per package.

Figure 3 illustrates some examples of Network Controller configurations supported by the NC-SI in the current release:

- Configuration 1 shows a Management Controller connecting to a single Network Controller with a single external network connection.
- Configuration 2 shows a Management Controller connecting to a Network Controller package that supports two NC-SI channel connections.
- Configuration 3 shows a Management Controller connecting to four discrete Network Controllers.

Configuration 1: Single Channel, Single Package

Configuration 2: Integrated Dual Channel, Single Package

Configuration 3: Single Channels, Four Discrete Packages

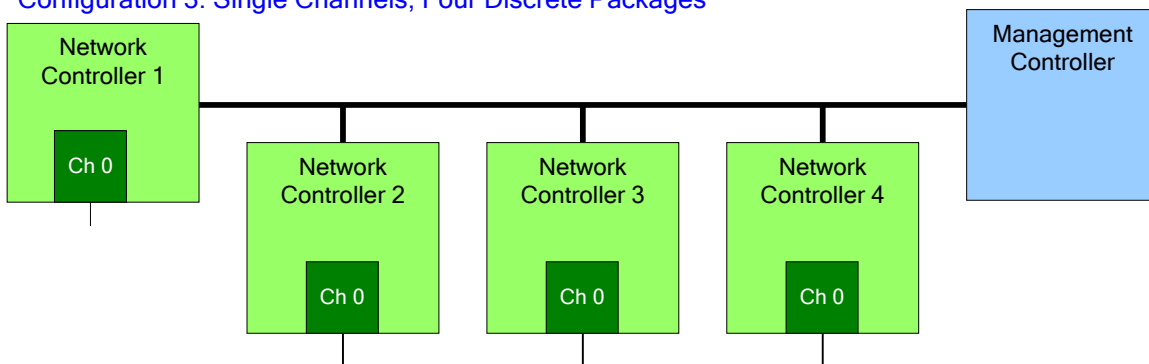

Figure 3 – Example topologies supported by the NC-SI

### 5.3 Single and integrated Network Controller implementations

This clause illustrates the general relationship between channels, packages, receive buffers, and bus buffers for different controller implementations.

1021 An integrated controller is a Network Controller that connects to the NC-SI RBT (or other physical  
 1022 interfaces that support NC-SI) interface and provides NC-SI support for two or more network connections.  
 1023 A single controller is a controller that supports only a single NC-SI channel.

1024 For the *NC-SI Specification*, an integrated controller can be logically implemented in one of three basic  
 1025 ways, as illustrated in Figure 4. Although only two channels are shown in the illustration, an integrated  
 1026 controller implementation can provide more than two channels. The example channel and package  
 1027 numbers (for example, channel 0, package 0) refer to the Internal Channel and Package ID subfields of  
 1028 the Channel ID. For more information, see clause 6.1.9.

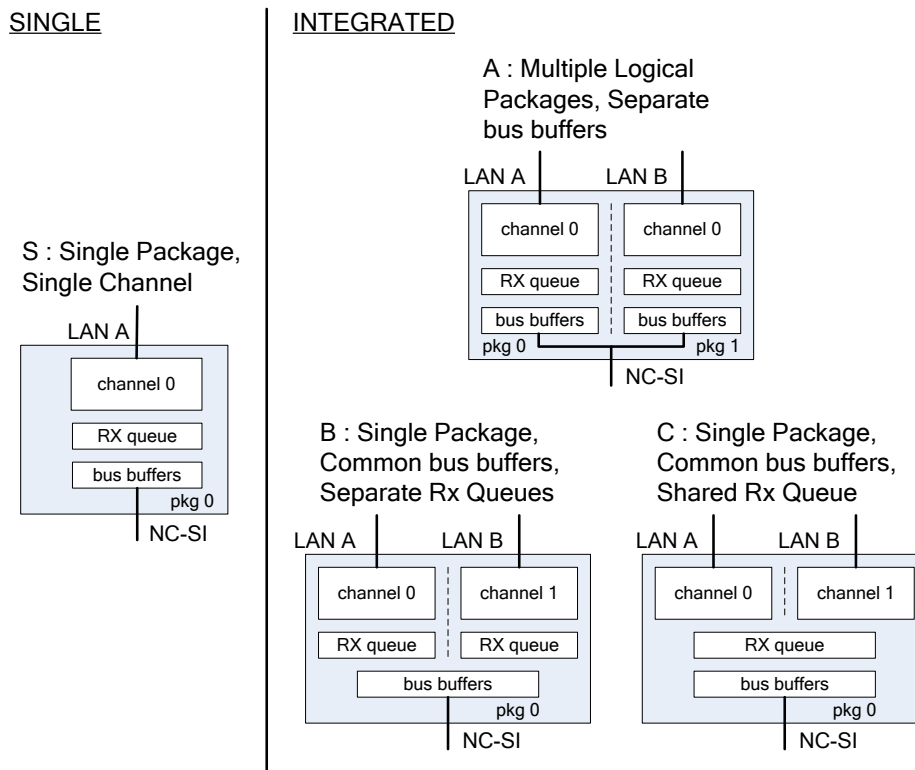

Figure 4 – Network Controller integration options

1031 Packages that include multiple channels are required to handle internal arbitration between those  
 1032 channels and the Sideband Interface. The mechanism by which this occurs is vendor-specific and not  
 1033 specified in this document. This internal arbitration is always active by default. No NC-SI commands are  
 1034 defined for enabling or disabling internal arbitration between channels.

1035 The following classifications refer to a logical definition. The different implementations are distinguished  
 1036 by their behavior with respect to the NC-SI bus and command operation. The actual physical and internal  
 1037 implementation can vary from the simple diagrams. For example, an implementation can act as if it has  
 1038 separate RX queues without having physically separated memory blocks for implementing those queues.

- **S: Single Package, Single Channel**

This implementation has a single NC-SI interface providing NC-SI support for a single LAN port, all contained within a package or module that has a single connection to the NC-SI physical

bus. Note that FC Bonding is supported in this specification and thus multiple physical ports may be aggregated into one logical port.

- **A: Multiple Logical Packages, Separate Bus Buffers**

This implementation acts like two physically separate Network Controllers that happen to share a common overall physical container. Electrically, they behave as if they have separate electrical buffers connecting to the NC-SI bus. This behavior might be accomplished by means of a passive internal bus or by separate physical pins coming from the overall package. From the point of view of the Management Controller and the NC-SI command operation, this implementation behaves as if the logical controllers were implemented as physically separate controllers.

This type of implementation could include internal hardware arbitration between the two logical Network Controller packages. If hardware arbitration is provided external to the package, it shall meet the requirements for hardware arbitration described later in this specification. (For more information, see clause 7.3.)

- **B: Single Package, Common Bus Buffers, Separate RX Queues**

In this implementation, the two internal NC-SI channels share a common set of electrical bus buffers. A single Deselect Package command will deselect the entire package. The Channel Enable and Channel Disable commands to each channel control whether the channel can transmit Pass-through and AEN packets through the NC-SI interface. The Channel Enable command also determines whether the packets to be transmitted through the NC-SI interface will be queued up in an RX Queue for the channel while the channel is disabled or while the package is deselected. Because each channel has its own RX Queue, this queuing can be configured for each channel independently.

- **C: Single Package, Common Bus Buffers, Shared RX Queue**

This implementation is the same as described in the preceding implementation, except that the channels share a common RX Queue for holding Pass-through packets to be transmitted through the NC-SI interface. This queue could also queue up AEN or Response packets.

In addition to the general purpose architectures listed above, some Network Controllers support more advanced architectures that provide for multiple host interfaces that share a single channel/physical port (commonly called partitions), a single host interface that sends and receives traffic over multiple physical ports, but modeled as a single channel, and lastly an internally terminated channel that can be used to control some other functionality in the NC that requires a communication and control path to the MC.

## 5.4 Transport stack

The overall transport stack of the NC-SI is illustrated in Figure 5. The lowest level is the physical-level interface (for example, RBT), and the media-level interface is based on Ethernet. Above these interfaces are the two data-level protocols that are supported by the *NC-SI Specification*: NC-SI Command Protocol and the Network Data Protocol (for example, ARP, IP, DHCP, and NetBIOS) associated with Pass-through traffic for NCs supporting Ethernet. Both protocols are independent from binding to the underlying physical interface. This specification only defines the binding for NC-SI over RBT.

This document defines the necessary NC-SI command set and interface specification that allows the appropriate configuration of the Network Controller parameters and operation to enable network traffic to flow to and from external networks to the Management Controller for those devices that support it. As shown in Figure 5, the scope of the NC-SI Command Protocol is limited to the interface between the Network Controller and the Management Controller.

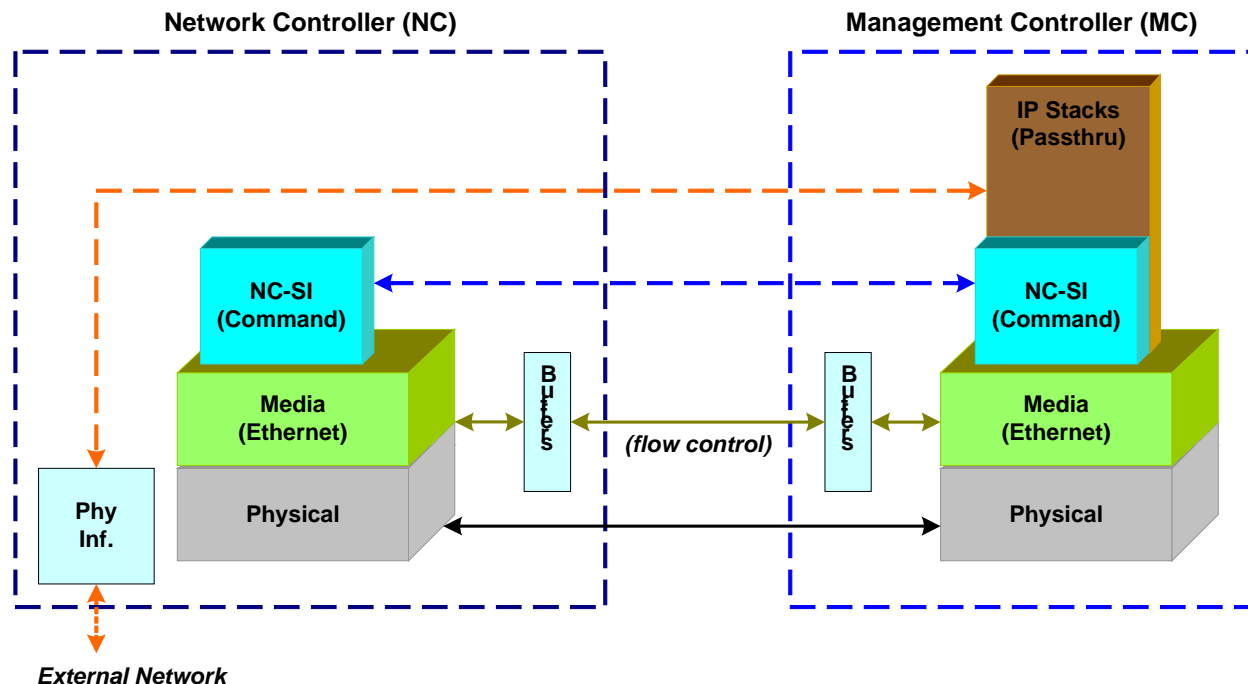

Figure 5 – NC-SI transport stack

## 5.5 Transport protocol

A simple transport protocol is used to track the reliable reception of command packets. The transport protocol is based upon a command/response paradigm and involves the use of unique Instance IDs (IIDs) in the packet headers to allow responses received to be matched to previously transmitted commands. The Management Controller is the generator of command packets sent to the Sideband Interface of one or more Network Controllers in the system, and it receives response packets from them. A response packet is expected to be received for every command packet successfully sent.

The transport protocol described here shall apply only to command and response packets sent between the Management Controller and the Network Controller.

## 5.6 Byte and bit ordering for transmission

Unless otherwise specified, the bytes for a multi-byte numeric field are transmitted most significant byte first and bits within a byte are transmitted most significant bit first.

## 6 Operational behaviors

### 6.1 Typical operational model

This clause describes the typical system-level operation of the NC-SI components.

The following tasks are associated with Management Controller use of the NC-SI:

- **Initial configuration**

When the NC-SI interface is first powered up, the Management Controller needs to discover and configure NC-SI devices as well as to enable pass-through operation. This task includes setting parameters such as MAC addresses, configuring Layer 2 filtering, setting Channel enables, and so on.

- **General Controller configuration and monitoring**

The Management Controller may also configure and monitor aspects of Controller operation.

- **Pass-through**

The Management Controller handles transmitting and receiving Pass-through packets using the NC-SI. Pass-through packets can be delivered to and received from the network through the NC-SI based on the Network Controller's NC-SI configuration.

- **Asynchronous event handling**

In certain situations, a status change in the Network Controller, such as a Link State change, can generate an asynchronous event on the Sideband Interface. These event notifications are sent to the Management Controller where they are processed as appropriate.

- **Error handling**

The Management Controller handles errors that could occur during operation or configuration. For example, a Network Controller might have an internal state change that causes it to enter a state in which it requires a level of reconfiguration (this condition is called the "Initial State," described in more detail in 6.1.4); or a data glitch on the NC-SI could have caused an NC-SI command to be dropped by the Network Controller, requiring the Management Controller to retry the command.

#### 6.1.1 State definitions and defined states

Table 1 describes states related to whether and when the Network Controller is ready to handle NC-SI command packets, when it is allowed to transmit packets through the NC-SI interface, and when it has entered a state where it is expecting configuration by the Management Controller.

**Table 1 – NC-SI operating state descriptions**

State	Applies to	Description
Interface Power Down	Package	The NC-SI is in the power down state.
Interface Power Up	Package	The NC-SI is in the power up state, as defined in clause 10.
Package Selected (also referred to as the Selected state)	Package	A Selected package is allowed to turn on its electrical buffers and transmit through the NC-SI interface.
Package Deselected (also referred to as the Deselected state)	Package	A Deselected package is not allowed to turn on its electrical buffers and transmit through the NC-SI interface.

State	Applies to	Description
Hardware Arbitration Enabled	Package	When hardware arbitration is enabled, the package is allowed to transmit through the NC-SI interface only when it is Selected and has the TOKEN opcode.
Hardware Arbitration Disabled	Package	When hardware arbitration is disabled, the package is allowed to transmit through the NC-SI interface anytime that it is Selected, regardless of whether it has the TOKEN opcode.
Package Ready	Package	In the Package Ready state, the package is able to accept and respond to NC-SI commands for the package and be Selected.
Package Not Ready	Package	The Package Not Ready state is a transient state in which the package does not accept package-specific commands.
Channel Ready	Channel	In the Channel Ready state, a channel within the package is able to accept channel-specific NC-SI commands that are addressed to its Channel ID (Package ID + Internal Channel ID).
Channel Not Ready	Channel	The Channel Not Ready state is a transient state in which the channel does not accept channel-specific commands.
Initial State	Channel	In the Initial State, the channel is able to accept and respond to NC-SI commands, and one or more configuration settings for the channel need to be set or restored by the Management Controller (that is, the channel has not yet been initialized, or has encountered a condition where one or more settings have been lost and shall be restored). Refer to 6.1.4 for more information.
Channel Enabled	Channel	This is a sub-state of the Channel Ready state. When a channel is enabled, the channel is allowed to transmit unrequested packets (that is, packets that are not command responses — for example, AEN and Pass-through packets) through the NC-SI interface whenever the package is Selected.
Channel Disabled	Channel	This is a sub-state of the Channel Ready state. When a channel is disabled, the channel is not allowed to transmit unrequested packets (that is, packets that are not command responses — for example, AEN and Pass-through packets) through the NC-SI interface.

## 6.1.2 NC-SI RBT pre-operational states

There are two states defined on RBT before it becomes operational:

- NC-SI Interface Power Down state

In this state, the NC-SI Physical interface and the associated receive and transmit buffers in all devices on the NC-SI RBT (that is, the NC-SI interfaces on the Network Controllers and Management Controller) are not powered up.

- NC-SI Power Up state

In this state, the NC-SI Physical interface and the associated receive and transmit buffers in all devices on the NC-SI RBT (that is, the Network Controller and Management Controller) are powered up.

NOTE: NC transmit I/O buffers should not be enabled in this state. The Network Controller is expected to transition to the Initial State within T4 seconds after the Power Up state is entered.

## 6.1.3 Package Ready state

A Network Controller in the Package Ready state shall be able to respond to any NC-SI commands that are directed to the ID for the overall package (versus being directed to a particular channel within the

1147 package). Package-specific commands are identified by a particular set of Channel ID values delivered in  
 1148 the command header (see clause 6.1.9).

#### 1149 **6.1.4 Initial State**

1150 The Initial State for a channel corresponds to a condition in which the Sideband Interface is powered up  
 1151 and is able to accept NC-SI commands, and the channel has one or more configuration settings that need  
 1152 to be set or restored by the Management Controller. Unless default configuration settings are explicitly  
 1153 defined in this specification, the default values are implementation specific. The MC should not make any  
 1154 assumptions on any configuration settings that are not defined in this specification. Because this state  
 1155 may be entered at any time, the Initial State shall be acknowledged with a Clear Initial State command for  
 1156 the Initial State to be exited. This requirement helps to ensure that the Management Controller does not  
 1157 continue operating the interface unaware that the NC-SI configuration had autonomously changed in the  
 1158 Network Controller.

1159 An NC-SI channel in the Initial State shall:

- 1160 • be able to respond to NC-SI commands that are directed to the Channel ID for the particular  
 1161 channel (see clause 6.1.9)

- 1162 • respond to all non-OEM NC-SI command packets that are directed to the channel or partitions  
 1163 on the channel with a Response Packet that contains a Response Code of “Command Failed”  
 1164 and a Reason Code of “Initialization Required”

1165 NOTE: This requirement does not apply to commands that are directed to the overall package, such as the  
 1166 Select Package and Deselect Package commands.

- 1167 • place the channel into the Disabled state

- 1168 • set hardware arbitration (if supported) to “enabled” on Interface Power Up only; otherwise, the  
 1169 setting that was in effect before entry into the Initial State shall be preserved (that is, the  
 1170 hardware arbitration enable/disable configuration is preserved across entries into the Initial  
 1171 State)

- 1172 • set the enabled/disabled settings for the individual MAC and VLAN filters (typically set using the  
 1173 Set MAC Address, Set VLAN Filter, and Enable VLAN commands) to “disabled”

1174 NOTE It is recommended that global multicast and broadcast filters are also set to “disabled”.

- 1175 • reset all counters defined in the various channel and partition level statistics commands, and the  
 1176 Get NC-SI Pass-Through Statistics command to 0x0

- 1177 • disable the Channel Network TX setting and transmission of Pass-through packets onto the  
 1178 network

- 1179 • clear any record of prior command instances received upon entry into the Initial State (that is,  
 1180 assume that the first command received after entering the Initial State is a new command and  
 1181 not a retried command, regardless of any Instance ID that it may have received before entering  
 1182 the Initial State)

- 1183 • disable transmission of AENs and reset any enabled AENs

1184 Otherwise, there is no requirement that other NC-SI configuration settings be set, retained, or restored to  
 1185 particular values in the Initial State unless otherwise specified. Controller configuration settings that are  
 1186 identified as persistent and saved to NVRAM are one example of retained settings..

1187 The Initial State is a NC-SI configuration state and therefore places no requirements on the NC's network  
 1188 link state.

### 1189 6.1.5 NC-SI Initial State recovery

1190 As described in clause 6.1.4, a channel in the Initial State shall receive the Clear Initial State command  
1191 before other commands can be executed. This requirement ensures that if the Initial State is entered  
1192 asynchronously, the Management Controller is made aware that one or more NC-SI settings may have  
1193 changed without its involvement and blocks the Management Controller from issuing additional  
1194 commands under that condition. Until the channel receives the Clear Initial State command, the Network  
1195 Controller shall respond to any other received command (except the Select Package and Deselect  
1196 Package commands) with a Command Failed response code and Interface Initialization Required reason  
1197 code to indicate that the Clear Initial State command shall be sent. See response and reason code  
1198 definitions in clause 8.2.5.2.

1199 NOTE: This requirement does not apply to commands that are directed to the overall package, such as the Select  
1200 Package and Deselect Package commands.

1201 If the Management Controller, at any time, receives the response indicating that the Clear Initial State  
1202 command is expected, it should interpret this response to mean that default settings have been restored  
1203 for the channel (per the Initial State specification), and that one or more package/channel settings need to  
1204 be restored by the Management Controller.

### 1205 6.1.6 State transition diagram

1206 Figure 6 illustrates the general relationship between the package- and channel-related states described in  
1207 Table 1 and the actions that cause transitions between the states. Each bubble in Figure 6 represents a  
1208 particular combination of states as defined in Table 1.

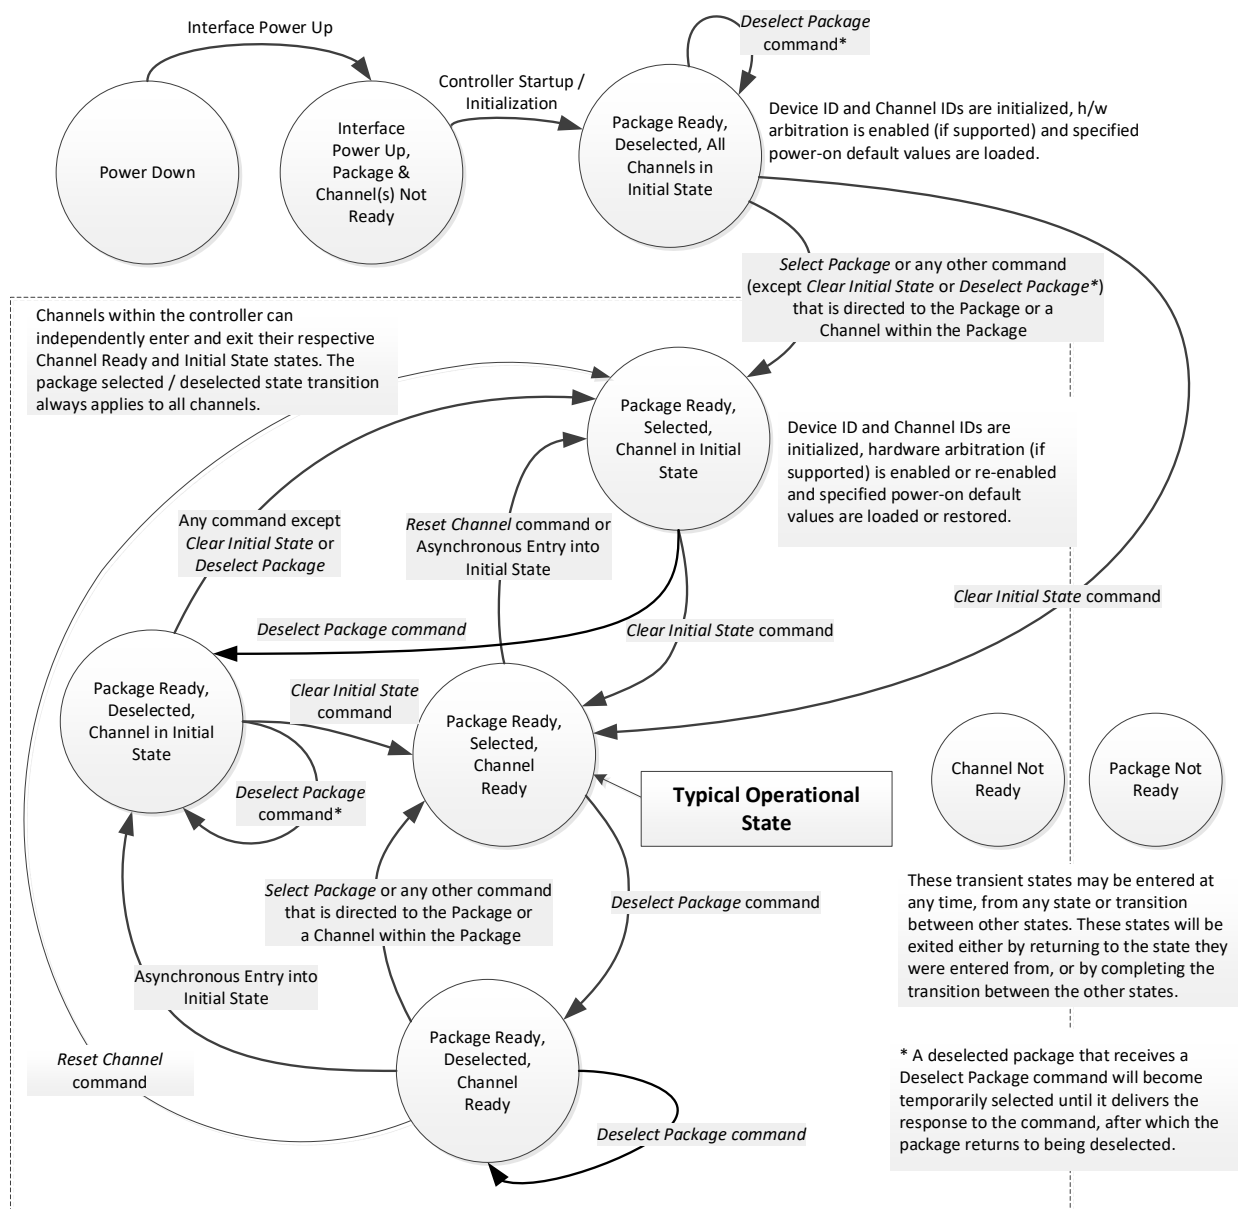

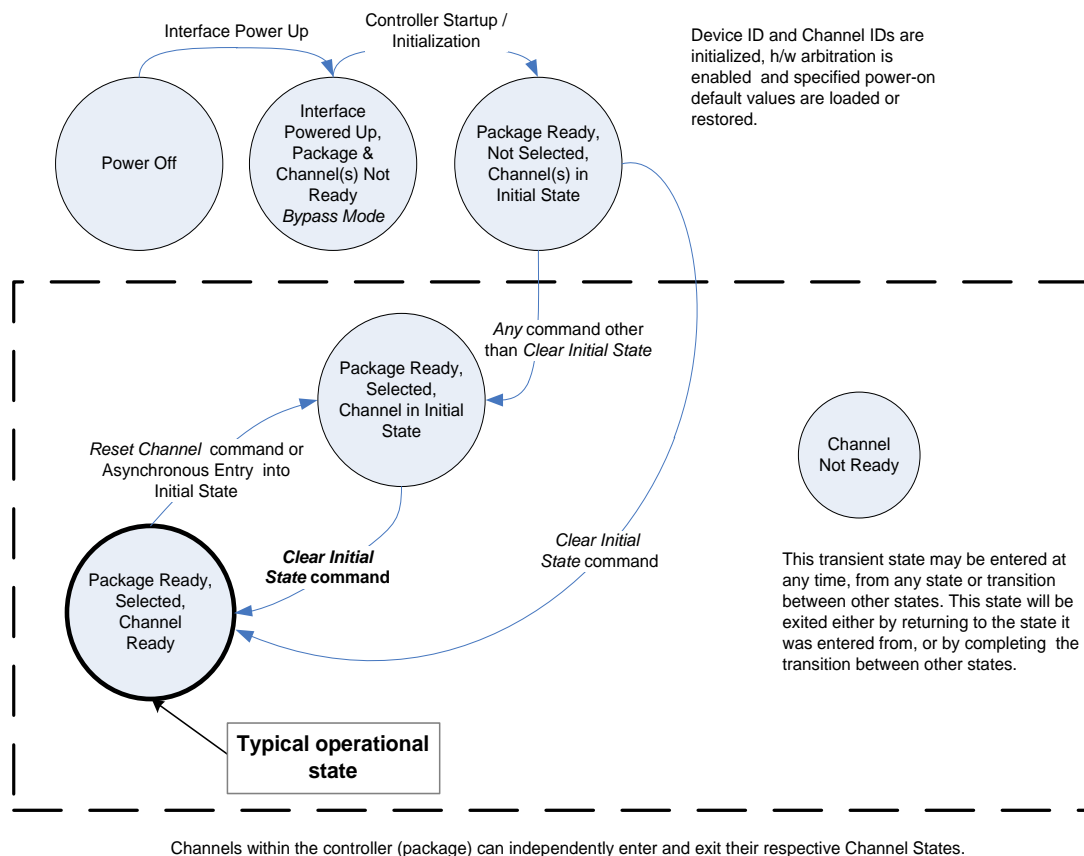

Figure 6 – NC-SI package/channel operational state diagram

### 6.1.7 State diagram for NC-SI operation with hardware arbitration

Figure 7 shows NC-SI operation in the hardware arbitration mode of operation. This is a sub-set of the general NC-SI operational state diagram (Figure 6) and has been included to illustrate the simplified sequence of package selection when this optional capability is used.

**Figure 7 – NC-SI operational state diagram for hardware arbitration operation**

While Select and Deselect package commands are not shown in Figure 7, these commands can be used with HW arbitration and will behave as specified in this specification.

Select and Deselect package commands can work together with HW arbitration. If HW arbitration is enabled, a package needs both the HW arbitration token and to be selected in order to transmit on the NC-SI RBT. If either the package is deselected, or the package does not have HW arbitration token, then the package is not allowed to transmit on the NC-SI RBT.

## 6.1.8 Resets

### 6.1.8.1 Asynchronous entry into Initial State

An Asynchronous Reset event is defined as an event that results in a Channel asynchronously entering the Initial State. This event could occur as a consequence of powering up, a System Reset, a Driver Reset, an internal firmware error, loss of configuration errors, internal hardware errors, and so on. Additionally, it is recommended that any event in the NC that causes a total or partial loss of configuration should be interpreted as an Asynchronous Reset event

Unless otherwise specified, NC-SI configuration settings beyond those required by the Initial State may or may not be preserved following asynchronous entry into the Initial State, depending on the Network Controller implementation.

There is no explicit definition of a Reset for an entire package. However, it is possible that an Asynchronous Reset condition may cause an asynchronous entry into the Initial State for all Channels in a package simultaneously.

### 6.1.8.2 Synchronous Reset

A Synchronous Reset event on the NC-SI is defined as a Reset Channel command issued by a Management Controller to a Channel. Upon the receipt of this command, the Network Controller shall place the Channel into the Initial State.

Unless otherwise specified, NC-SI configuration settings beyond those required by the Initial State may or may not be preserved following a Synchronous Reset, depending on the Network Controller implementation.

### 6.1.8.3 Other Resets

Resets that do not affect NC-SI operation are outside the scope of this specification.

## 6.1.9 Network Controller Channel ID

Each channel in the Network Controller shall be physically assigned a Network Controller Channel ID that will be used by the Management Controller to specify which Network Controller channel, of possibly many, it is trying to communicate. The Network Controller Channel ID shall be physically assignable (configured) at system-integration time based on the following specification.

It is the system integrator's or system designer's responsibility to correctly assign and provide these identifier values in single- and multi-port Network Controller configurations, and to ensure that Channel IDs do not conflict between devices sharing a common NC-SI RBT interconnect.

The Channel ID field is comprised of two subfields, Package ID and Internal Channel ID, as described in Table 2.

1255

Table 2 – Channel ID format

Bits	Field Name	Description
[7..5]	Package ID	<p>The Package ID is required to be common across all channels within a single Network Controller that share a common NC-SI physical interconnect.</p> <p>The system integrator will typically configure the Package IDs starting from 0 and increasing sequentially for each physical Network Controller.</p> <p>The Network Controller shall allow the least significant two bits of this field to be configurable by the system integrator, with the most significant bit of this field = 0b. An implementation is allowed to have all 3 bits configurable.</p>
[4..0]	Internal Channel ID	<p>The Network Controller shall support Internal Channel IDs that are numbered starting from 0 and increasing sequentially for each channel supported by the Network Controller that is accessible by the Management Controller through the NC-SI using NC-SI commands.</p> <p>An implementation is allowed to support additional configuration options for the Internal Channel ID as long as the required numbering can be configured.</p> <p>An Internal Channel ID value of 0x1F applies to the entire Package.</p>

1256 Channel IDs shall be completely decoded. Aliasing between values is not allowed (that is, the Network  
 1257 Controller is not allowed to have multiple IDs select the same channel on a given Sideband Interface).

1258 Once configured, the settings of the Package ID and Internal Channel ID values shall be retained in a  
 1259 non-volatile manner. That is, they shall be retained across power-downs of the Sideband Interface and  
 1260 shall not be required to be restored by the Management Controller for NC-SI operation. This specification  
 1261 does not define the mechanism for configuring or retaining the Package ID or the Internal Channel ID (if  
 1262 configurable). Some implementations may use pins on the Network Controller for configuring the IDs,  
 1263 other implementations may use non-volatile storage logic such as electrically erasable memory or  
 1264 FLASH, while others may use a combination of pins and non-volatile storage logic.

## 1265 6.1.10 Configuration-related settings

### 1266 6.1.10.1 Package-specific operation

1267 There are some NC-SI configuration settings that are package-specific:

- 1268 • the enable/disable settings for hardware arbitration
- 1269 • NC-SI flow control
- 1270 • Package-related AENs

1271 There may also be NC configuration settings that are controlled by NC-SI Commands addressed to the  
 1272 package. These commands specify this requirement in their command description.

1273 Hardware arbitration is enabled or disabled through a parameter that is delivered using the Select  
 1274 Package command. If hardware arbitration is enabled on all Network Controller packages on the NC-SI  
 1275 RBT, more than one package can be in the Selected state simultaneously. Otherwise, only one package  
 1276 is allowed to be in the Selected state at a time in order to prevent electrical buffer conflicts (buffer fights)  
 1277 that can occur from more than one package being allowed to drive the bus.

1278 NC-SI flow control is enabled or disabled using the Set NC-SI Flow Control command. The flow control  
 1279 setting applies to all channels in the package.

1280 Package-specific commands should only be allowed and executed when the Internal Channel ID field is  
 1281 set to 0x1F.

There are some package-level AENs to allow the NC to alert the MC of controller-level events.

### 6.1.10.2 Channel-specific operation

Channel-specific commands should only be allowed to be executed when the Internal Channel ID field is set to a value other than 0x1F. Channel-specific commands with Invalid Channel IDs are not allowed (see clause 6.9.2.1).

Table 3 shows the major categories of configuration settings that control channel operation when a channel is in the Channel Ready state. Channels that are not operating in Ethernet mode may not support Pass-through-related settings.

**Table 3 – Channel Ready state configuration settings**

Setting/Configuration Category	Description
“Channel Enable” settings	The Enable Channel and Disable Channel commands are used to control whether the channel is allowed to asynchronously transmit unrequested packets (AEN and Pass-through packets) through the NC-SI interface whenever the package is Selected. Note that channels are always allowed to transmit responses to commands sent to the channel.
“Channel Configuration” settings	Version 1.2 adds a number of commands for configuration setting of channels and their partitions (if supported) See Table 19
Pass-through Transmit Enable settings	The Enable Channel Network TX command is used to enable the channel to transmit any Pass-through packets that it receives through the NC-SI onto the network, provided that the source MAC address in those packets matches the Network Controller settings. Correspondingly, the Disable Channel Network TX command is used to direct the controller not to transmit Pass-through packets that it receives onto the network.
AEN Enable settings	The AEN Enable command is used to enable and disable the generation of the different AENs supported by the Network Controller.
MAC Address Filter settings and control	The Set MAC Address, Enable Broadcast Filter, and Enable Global Multicast Filter commands are used to configure the filters for unicast, broadcast, and multicast addresses that the controller uses in conjunction with the VLAN Filter settings for filtering incoming Pass-through packets.
VLAN Filter settings and control	The Set VLAN Filter command is used to configure VLAN Filters that the controller uses in conjunction with the MAC Address Filters for filtering incoming Pass-through packets. The Enable VLAN and Disable VLAN commands are used to configure VLAN filtering modes and enable or disable whether VLAN filtering is used.

### 6.1.11 Transmitting Pass-through packets from the Management Controller

Packets not recognized as command packets (that is, packets without the NC-SI Ethertype) that are received on the Network Controller’s NC-SI interface shall be assumed to be Pass-through packets provided that the source MAC Address matches one of the unicast MAC addresses settings (as configured by the Set MAC Address command) for the channel in the Network Controller, and will be forwarded for transmission to the corresponding external network interface if Channel Network TX is enabled.

### 6.1.12 Receiving Pass-through packets for the Management Controller

The Management Controller has control over and responsibility for configuring packet-filtering options, such as whether broadcast, multicast, or VLAN-tagged packets are accepted. Depending on the filter

1301 configurations, after the channel has been enabled, any packet that the Network Controller receives for  
1302 the Management Controller shall be forwarded to the Management Controller through the NC-SI  
1303 interface.

### 1304 **6.1.13 Pass-through operation in multiple medium implementations**

1305 Pass-through operation is not restricted to certain physical interfaces, but a NC-SI channel shall support  
1306 Pass-through on at most one physical interface at a time.

### 1307 **6.1.14 Startup sequence examples**

#### 1308 **6.1.14.1 Overview**

1309 The following clauses show possible startup sequences that may be used by the Management Controller  
1310 to start NC-SI operation. Depending upon the specific configuration of each system, there are many  
1311 possible variations of startup sequences that may be used, and these examples are intended for  
1312 reference only.

#### 1313 **6.1.14.2 Typical non-hardware arbitration specific startup sequence**

1314 The following sequence is provided as an example of one way a Management Controller can start up  
1315 NC-SI operation. This sequence assumes that the Management Controller has no prior knowledge of how  
1316 many Network Controllers are present on RBT, or what capabilities those controllers support. Note that  
1317 this is not the only possible startup sequence. Alternative sequences can also be used to start up NC-SI  
1318 operation. Some steps may be skipped if the Management Controller has prior knowledge of the Network  
1319 Controller capabilities, such as whether Network Controllers are already connected and enabled for  
1320 hardware arbitration.

##### 1321 1) Power up

1322 The NC-SI is powered up (refer to clause 10.2.8 for the specification of this condition). The  
1323 Network Controller packages are provided a Network Controller Power Up Ready Interval  
1324 during which they can perform internal firmware startup and initialization to prepare their NC-SI  
1325 to accept commands. The Management Controller first waits for the maximum Network  
1326 Controller Power Up Ready Interval to expire (refer to Table 278). At this point, all the Network  
1327 Controller packages and channels should be ready to accept commands through the NC-SI.  
1328 (The Management Controller may also start sending commands before the Network Controller  
1329 Power Up Ready Interval expires but will have to handle the case that Network Controller  
1330 devices may be in a state in which they are unable to accept or respond to commands.)

##### 1331 2) Discover package

1332 The Management Controller issues a Select Package command starting with the lowest  
1333 Package ID (see clause 8.5.5 for more information). Because the Management Controller is  
1334 assumed to have no prior knowledge of whether the Network Controller is enabled for hardware  
1335 arbitration, the Select Package command is issued with the Hardware Arbitration parameter set  
1336 to 'disable'.

1337 If the Management Controller receives a response within the specified response time, it can  
1338 record that it detected a package at that ID. If the Management Controller does not receive a  
1339 response, it is recommended that the Management Controller retry sending the command.  
1340 Three total tries are typical. (This same retry process should be used when sending all  
1341 commands to the Network Controller and will be left out of the descriptions in the following  
1342 steps.) If the retries fail, the Management Controller can assume that no Network Controller is at  
1343 that Package ID and can immediately repeat this step 2) for the next Package ID in the  
1344 sequence.

##### 1345 3) Discover and get capabilities for each channel in the package

1346 The Management Controller can now discover how many channels are supported in the  
 1347 Network Controller package and their capabilities. To do this, the Management Controller issues  
 1348 the Clear Initial State command starting from the lowest Internal Channel ID (which selects a  
 1349 given channel within a package). If it receives a response, the Management Controller can then  
 1350 use the Get Version ID command to determine NC-SI specification compatibility, and the Get  
 1351 Capabilities command to collect information about the capabilities of the channel. The  
 1352 Management Controller can then repeat this step until the full number of internal channels has  
 1353 been discovered. (The Get Capabilities command includes a value that indicates the number of  
 1354 channels supported within the given package.)

1355 NOTE The *NC-SI Specification* requires Network Controllers to be configurable to have their Internal  
 1356 Channel IDs be sequential starting from 0. If it is known that the Network Controller is configured this way,  
 1357 the Management Controller needs only to iterate sequentially starting from Internal Channel  
 1358 ID = 0 up to the number of channels reported in the first Get Capabilities response.

1359 The Management Controller should temporarily retain the information from the Get Capabilities  
 1360 command, including the information that reports whether the overall package supports hardware  
 1361 arbitration. This information is used in later steps.

1362 4) Repeat steps 2 and 3 for remaining packages

1363 The Management Controller repeats steps 2) and 3) until it has gone through all the Package  
 1364 IDs.

1365 IMPORTANT: Because hardware arbitration has not been enabled yet, the Management  
 1366 Controller shall issue a Deselect Package command to the present Package ID before issuing  
 1367 the Select Package command to the next Package ID. If hardware arbitration is not being used,  
 1368 only one package can be in the Selected state at a time. Otherwise, hardware electrical buffer  
 1369 conflicts (buffer fights) will occur between packages.

1370 5) Initialize each channel in the package

1371 Based on the number of packages and channels that were discovered, their capabilities, and  
 1372 the desired use of Pass-through communication, the Management Controller can initialize the  
 1373 settings for each channel. This process includes the following general steps for each package:

1374 a) Issue the Select Package command.

1375 b) For each channel in the package, depending on controller capabilities, perform the  
 1376 following actions. Refer to individual command descriptions for more information.

1377 • Use the Set MAC Address command to configure which unicast and multicast  
 1378 addresses are used for routing Pass-through packets to and from the Management  
 1379 Controller.

1380 • Use the Enable Broadcast Filter command to configure whether incoming broadcast  
 1381 Pass-through packets are accepted or rejected.

1382 • Use the Enable Global Multicast Filter command to configure how incoming multicast  
 1383 Pass-through packets are handled based on settings from the Set MAC Address  
 1384 command.

1385 • Use the Set VLAN Filter and Enable VLAN Filters commands to configure how  
 1386 incoming Pass-through packets with VLAN Tags are handled.

1387 • Use the Set NC-SI Flow Control command (if supported) to configure how Ethernet  
 1388 Pause Frames are used for flow control on RBT. Set NC-SI Flow Control is a package  
 1389 command and only needs to be issued once.

1390 • Use the AEN Enable command to configure what types of AEN packets the channel  
 1391 should send out on the NC-SI.

- 1392                   • Use the Enable Channel Network TX command to configure whether the channel is  
1393                   enabled to deliver Pass-through packets from the NC-SI to the network (based on the  
1394                   MAC address settings) or is disabled from delivering any Pass-through packets to the  
1395                   network.

1396                   c) Issue the Deselect Package command.

1397                   6) Start Pass-through packet and AEN operation on the channels

1398                   The channels should now have been initialized with the appropriate parameters for Pass-  
1399                   through packet reception and AEN operation. Pass-through operation can be started by issuing  
1400                   the Enable Channel command to each channel that is to be enabled for delivering Pass-through  
1401                   packets or generating AENs through the NC-SI interface.

1402                   NOTE: If hardware arbitration is not operational and it is necessary to switch operation over to another package, a  
1403                   Deselect Package command shall be issued to the presently selected package before a different package can be  
1404                   selected. Deselecting a package blocks all output from the package. Therefore, it is not necessary to issue Disable  
1405                   Channel commands before selecting another package. There is no restriction on enabling multiple channels within a  
1406                   package.

#### 1407                   6.1.14.3 Hardware arbitration-specific startup sequence

1408                   This clause applies when multiple NCs are used by the MC. This clause only applies to the NC-SI over  
1409                   RBT binding.

1410                   The following is an example of the steps that a Management Controller may perform to start up NC-SI  
1411                   operation when Hardware Arbitration is specifically known to be used, present, and enabled on all  
1412                   Network Controllers. This example startup sequence assumes a high level of integration where the  
1413                   Management Controller knows the Network Controllers support and default to the use of Hardware  
1414                   Arbitration on startup but does not have prior knowledge of how many Network Controllers are present on  
1415                   RBT, or the full set of capabilities those controllers support, so discovery is still required.

1416                   Although other startup examples may show a specific ordering of steps for the process of discovering,  
1417                   configuring and enabling channels, the Management Controller has almost total flexibility in choosing how  
1418                   these steps are performed once a channel in a package is discovered. In the end, it would be just as valid  
1419                   for a Management Controller to follow a breadth-first approach to discovery steps as it would be to follow  
1420                   a depth-first approach where each channel that is discovered is fully initialized and enabled before  
1421                   moving to the next.

#### 1422                   1) Power up

1423                   No change from other startup scenarios.

#### 1424                   2) Discovery

1425                   The process of discovery consists of identifying the number of packages that are available, the  
1426                   number of channels that are available in each package, and for each channel, the capabilities  
1427                   that are provided for Management Controller use. Because, in this startup scenario, the  
1428                   Management Controller knows Hardware Arbitration is used, it is not required to use the **Select**  
1429                   **Package** and **Deselect Package** commands for discovery but may elect to just use the **Clear**  
1430                   **Initial State** command for this purpose instead.

1431                   In this startup scenario, Packages and Channels are discovered by sending the **Clear Initial**  
1432                   **State** command starting with the lowest Package ID and Internal Channel ID, then waiting for,  
1433                   and recording, the response event as previously described. Internal channel IDs are required to  
1434                   be numbered sequentially starting with 0, so when the Management Controller does not receive  
1435                   a response to repeated attempts at discovery, it knows this means no additional channels exist  
1436                   in the current package. If this happens when the internal channel ID is 0, the Management  
1437                   Controller knows a package is not available at the current package ID, and it continues with the

next package ID in sequence. If the Management Controller receives a response to the **Clear Initial State** command, it records that the channel and package are available, and continues discovery.

During discovery, the Management Controller should interrogate the capabilities of each channel found to be available in each package by sending the **Get Capabilities** command appropriate package and Internal channel ID values. However, it does not matter whether this is done as the very next step in the discovery process or performed for each channel after all packages and channels have been discovered, just as long as the Management Controller does interrogate each channel.

### 3) Configure each channel and enable pass-through

Once the existence of all packages and channels, and the capabilities of each channel, have been discovered and recorded, the Management Controller shall initialize and enable each channel as needed for use. The details of these steps remain essentially the same as have been previously stated, except to note that there are no restrictions on how they are performed. What this means is that the MC may perform these steps in any order across the channels in each package as it sees fit. The MC may fully initialize and enable each channel in each package one at a time or perform the same step on each channel in sequence before moving on to the next, or in a different order. The specific order of steps is not dictated by this specification.

#### 6.1.14.4 Summary of scheme for the MC without prior knowledge of hardware arbitration

The following scheme describes the case when the MC does not have a priori knowledge of the hardware arbitration support across multiple NCs.

1. For each available NC,
  - a. The MC checks whether a device supports the HW arbitration, using **“Get Capabilities”** command (this implicitly selects the package).
  - b. The MC issues **“Deselect Package”** for the NC (needed as at this stage we do not know whether all the devices support HW arbitration).
2. If (all NCs support HW arbitration and HW arbitration is used by all NCs), then

the MC assumes that HW arbitration is active because according to clause 6.2.4 “set hardware arbitration (if supported) to *enabled* on Interface Power Up only”, and the MC can “Select” any number of packages at the same time.
- Otherwise (at least one NC reports that HW arbitration is not supported, or at least one NC reports that HW arbitration is not used, or at least one NC cannot report its support level) then

HW arbitration is **not** active, and the MC can “Select” only single package at the any time.

The MC configures every NC to disable HW arbitration, using the **“Select Package”** command.

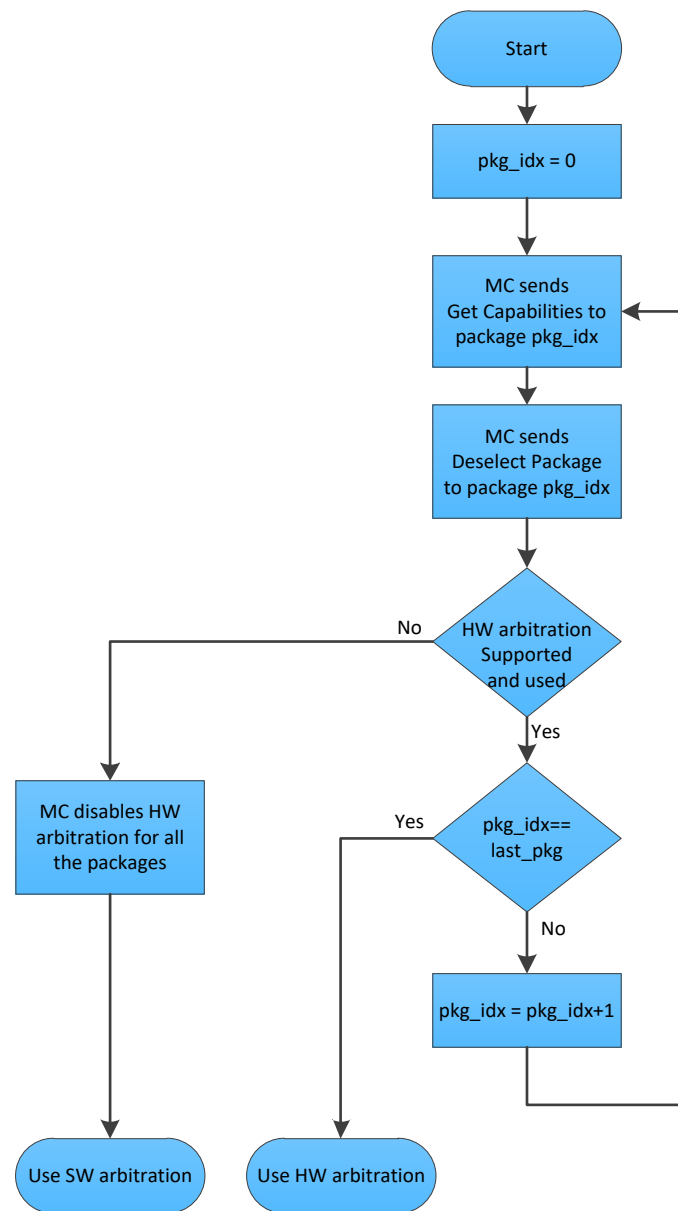

Figure 8 – MC steps when the MC does not have prior knowledge of hardware arbitration

## 6.2 NC-SI traffic types

### 6.2.1 Overview

Two types of traffic are defined by NC-SI, based on the network fabric type: Pass-through traffic and Control traffic.

- Pass-through traffic consists of packets that are transferred between the external network interface and the Management Controller using the Sideband Interface.
- Control traffic consists of commands (requests) and responses that support the inventory, configuration and control of the Network Controller, the Sideband Interface and Pass-through operation of the Network Controller, and AENs that support reporting various events to the Management Controller.

### 6.2.2 Command protocol

#### 6.2.2.1 Overview

Commands are provided to allow a Management Controller to initialize, control, and regulate Management Controller packet flow across the sideband interface, configure channel filtering, and to interrogate the operational status of the Network Controller. As interface master, the Management Controller is the initiator of all commands, and the Network Controller responds to commands, but may also generate AENs if enabled.

#### 6.2.2.2 Instance IDs

The command protocol uses a packet field called the Instance ID (IID). IID numbers are 8-bit values that shall range from 0x01 to 0xFF. IIDs are used to uniquely identify instances of a command, to improve the robustness of matching responses to commands, and to differentiate between new and retried commands. The Network Controller that receives a command handles the IID in the following ways:

- It returns the IID value from the command in the corresponding response.
- If the IID is the same as the IID for the previous command, it recognizes the command as a 'retried' command rather than as a new instance of the command. It is expected that the 'retried' command contains the same command type value in the Control Packet Type field. The NC behavior when a 'retried' command type does not match the original command type is outside the scope of this specification.
- If a retried command is received, the Network Controller shall return the previous response. Depending on the command, the Network Controller can accomplish this either by holding the previous response data so that it can be returned, or, if re-executing the command has no side effects (that is, the command is idempotent), by re-executing the command operation and returning that response.
- If the command IID is the same as the IID for the previous command, and the Poll Indication is set, the NC recognizes the command as a 'polling' command rather than as a new instance of the command.
  - When polling, the MC is expected to use the command type value of the original command in the Control Packet Type field. If there was no command in progress, the NC shall fail the 'polling' command and respond with an error. When the NC fails the 'polling' command, the outcome of the original command is indeterminate and is outside the scope of this specification.
  - If a command with Poll Indication set is received and the original command has been completed, then the Network Controller shall return the response of the completed command.

- 1520           • If it is still processing the command, it shall return a “Delayed Response” reason code and  
1521           optionally recommend a next polling time interval.
- 1522           • When an IID value is received that is different from the one for the previous command, the  
1523           Network Controller executes the command as a new command.
- 1524           • When the NC-SI Channel first enters the Initial State, it shall clear any record of any prior  
1525           requests. That is, it assumes that the first command after entering the Initial State is a new  
1526           command and not a retried command, regardless of any IID that it may have received before  
1527           entering the Initial State.

1528 Thus, for single-threaded operation with idempotent commands, a responding Network Controller can  
1529 simply execute the command and return the IID in the response that it received in the command. If it is  
1530 necessary to not execute a retried command, the responding controller can use the IID to identify the  
1531 retried command and return the response that was delivered for the original command.

1532 The Management Controller that generates a command handles the IID in the following ways:

- 1533           • The IID changes for each new instance of a command.
- 1534           • If a command needs to be retried, the Management Controller uses the same value for the IID  
1535           that it used for the initial command.
- 1536           • The Management Controller can optionally elect to use the IID to provide additional confirmation  
1537           that the response is being returned for a particular command.

1538 Because an AEN is not a response, an AEN always uses a value of 0x00 for its IID.

1539 NOTE: The Instance ID mechanism can be readily extended in the future to support multiple controllers and multiple  
1540 outstanding commands. This extension would require having the responder track the IID on a per command and per  
1541 requesting controller basis. For example, a retried command would be identified if the IID and command matched the  
1542 IID and command for a prior command for the given originating controller's ID. That is, a match is made with the  
1543 command, originating controller, and IID fields rather than on the IID field alone. A requester that generates multiple  
1544 outstanding commands would correspondingly need to track responses based on both command and IID to match a  
1545 given response with a given command. IIDs need to be unique for the number of different commands that can be  
1546 concurrently outstanding.

### 1547 6.2.2.3 Single-threaded operation

1548 The Network Controller is required to support NC-SI commands only in a single-threaded manner. That is,  
1549 the Network Controller is required to support processing only one command at a time and is not required  
1550 to accept additional commands until after it has sent the response to the previous one.

1551 Therefore, the Management Controller should issue NC-SI commands in a single-threaded manner. That  
1552 is, the Management Controller should have only one command outstanding to a given Network Controller  
1553 package at a time. Upon sending an NC-SI command packet, and before sending a subsequent  
1554 command, the Management Controller should wait for the corresponding response packet to be received  
1555 or a command timeout event to occur before attempting to send another command. For the full  
1556 descriptions of command timeout, see clause 6.9.3.2.

1557 NOTE: While NC implementations are only required to support single-threaded operations, they may choose to  
1558 support more than one outstanding command. The use of unique IIDs is essential to properly match multiple  
1559 outstanding commands and responses in such implementations.

### 1560 6.2.2.4 Responses

1561 The Network Controller shall process and acknowledge each validly formatted command received at the  
1562 NC-SI interface by formatting and sending a valid response packet to the Management Controller through  
1563 the NC-SI interface.

To allow the Management Controller to match responses to commands, the Network Controller shall copy the IID number of the Command into the Instance ID field of the corresponding response packet.

To allow for retransmission and error recovery, the Network Controller may re-execute the last command or maintain a copy of the response packet most recently transmitted to the Management Controller through its sideband interface. This “previous” response packet shall be updated every time a new response packet is transmitted to the Management Controller by replacing it with the one just sent.

The Network Controller shall return a “Command Unsupported” response code with an “Unknown Command Type” reason code for any command (standard or OEM) that the Network Controller does not support or recognize. If a command cannot be executed due to the processing of others, the response code Command Unavailable shall be returned.

#### 6.2.2.5 Response and post-response processing

Typically, a Network Controller completes a requested operation before sending the response. In some situations, however, it may be useful for the controller to be allowed to queue up the requested operation and send the response assuming that the operation will complete correctly (for example, when the controller is requested to change link configuration). The following provisions support this process:

- A Network Controller is allowed to send a response before performing the requested action if the command is expected to complete normally and all parameters that are required to be returned with the response are provided.
- Temporal ordering of requested operations shall be preserved. For example, if one command updates a configuration parameter value and a following command reads back that parameter, the operation requested first shall complete so that the following operation returns the updated parameter.
- Under typical operation of the Network Controller, responses should be delivered within the Normal Execution Interval (T5) (see Table 278).
- Unless otherwise specified, all requested operations shall complete within the Asynchronous Reset/Asynchronous Not Ready interval (T6) following the response.
- If the Network Controller channel determines that the requested operation or configuration change has not been completed correctly after sending the response, the channel shall enter the Initial State.
- If the command response is dependent on the execution of the command and the command response cannot be provided within Normal Execution Interval (T5), then a “Delayed Response” response code may be returned. In this case, the MC can poll the command later with the “Poll Indication” set to retrieve the response. The decision on when the MC polls again can be based on one of the following criteria:
  - A fixed delay. In this case a delay greater than T5 is recommended.
  - If provided, based on the “recommended next polling time” in the original response
  - If the AEN is enabled, based on reception of a “Delayed Response Ready AEN”

When using delayed responses, the NC shall complete the command processing within T14 sec.

#### 6.2.2.6 NC-SI traffic ordering

This specification does not require any ordering between AENs, NC-SI responses, and NC-SI Pass-through packets. Specific transport binding specifications may require ordering between AENs, NC-SI responses, and NC-SI Pass-through packets.

## 6.3 Link configuration and control

### 6.3.1 Link Configuration

The Network Controller provides commands to allow the Management Controller to specify the auto-negotiation, link speed, duplex settings, FEC algorithm, link training, SerDes lane configuration, and so on to be used on the network interface. For more information, see clause 8.5.21.

The Management Controller should make link configuration changes only when the host network driver is absent or non-operational.

### 6.3.2 Link Status

The Network Controller provides a Get Link Status command to allow the Management Controller to interrogate the configuration and operational status of the primary Ethernet links. The Management Controller may issue the Get Link Status command regardless of OS operational status.

## 6.4 Frame filtering for Pass-through mode

### 6.4.1 Overview

The Network Controller provides the option of configuring various types of filtering mechanisms for the purpose of controlling the delivery of received Ethernet frames to the Management Controller. These options include VLAN Tag filter, L2 address filters, MAC address support, and limited frame filtering using L3, L4 protocol header fields. All frames that pass frame filtering are forwarded to the Management Controller over the Sideband Interface. Refer to [RFC2373](#), [RFC2461](#), and [RFC3315](#) for IPv6-related definitions.

### 6.4.2 Multicast filtering

The Network Controller may provide commands to allow the Management Controller to enable and disable global filtering of all multicast packets. The Network Controller may optionally provide one or more individual multicast filters, as well as DHCP v6, IPv6 Neighbor Advertisement, IPv6 Router Advertisement, IPv6 Neighbor Solicitation, IPv6 MLD, mDNSv4, mDNSv6 and LLDP filters.

### 6.4.3 Broadcast filtering

The Network Controller provides commands to allow the Management Controller to enable and disable forwarding of Broadcast and ARP packets. The Network Controller may optionally support selective forwarding of broadcast packets for specific protocols, such as DHCP (see [RFC2131](#)) and NetBIOS.

### 6.4.4 VLAN filtering

The Network Controller provides commands to allow the Management Controller to enable and disable VLAN filtering, configure one or more VLAN Filters, and to configure VLAN filtering modes.

Figure 9 illustrates the flow of frame filtering. Italicized text in the figure is used to identify NC-SI command names.

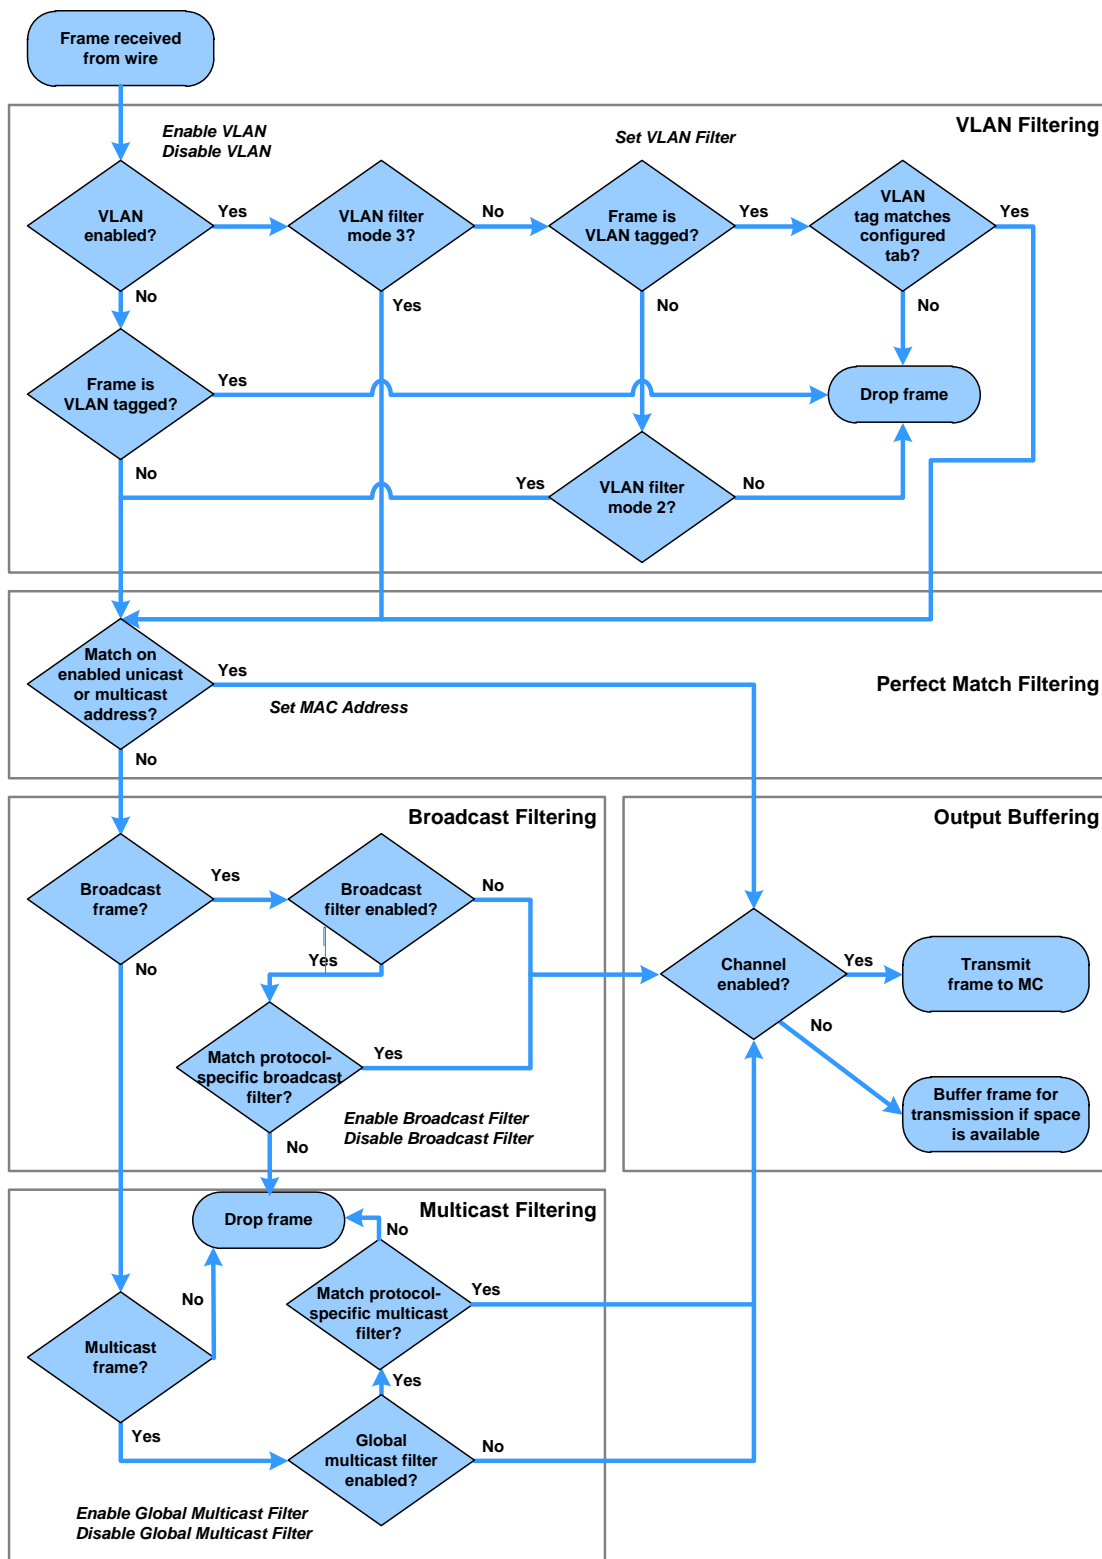

Figure 9 – NC-SI packet filtering flowchart

## 6.5 Output buffering behavior

There are times when the NC is not allowed to transmit Pass-through, AEN, or Control Packets onto the Sideband Interface.

The NC should buffer Pass-through frames to be transmitted to the MC under any of the following conditions:

- The package is deselected.
- For a channel within a package while that channel is disabled.
- When the hardware arbitration is enabled, and the NC does not have the token to transmit frames to the MC.

The NC may buffer AENs to the MC under any of the above conditions.

Control Packets (responses) are buffered when hardware arbitration is enabled, and the NC does not have the token to transmit frames to the MC.

Additionally, while an NC-SI channel is in the initial state, previously received Pass-through frames and AENs may or may not be buffered. This behavior is outside the scope of this specification.

## 6.6 NC-SI flow control

The Network Controller may provide commands to enable flow control on the RBT interface between the Network Controller and the Management Controller. The NC-SI flow control behavior follows the PAUSE frame behavior as defined in the [IEEE 802.3 specification](#). Flow control is configured using the Set NC-SI Flow command (see clause 8.5.41).

When enabled for flow control, a channel may direct the package to generate and renew 802.3x (XOFF) PAUSE Frames for a maximum interval of T12 for a single congestion condition. If the congestion condition remains in place after a second T12 interval expires, the congested channel shall enter the Initial State and remove its XOFF request to the package. Note that some implementations may have shared buffering arrangements where all channels within the package become congested simultaneously. Also note that if channels become congested independently, the package may not immediately go into the XON state after T12 if other channels within the package are still requesting XOFF.

## 6.7 Asynchronous Event Notification

Asynchronous Event Notification (AEN) packets enable the Network Controller to deliver unsolicited notifications to the Management Controller when certain status changes that could impact interface operation occur in the Network Controller. Because the NC-SI is a small part of the larger Network Controller, its operation can be affected by a variety of events that occur in the Network Controller. These events include link status changes, OS driver loads and unloads, and chip resets. This feature defines a set of notification packets that operate outside of the established command-response mechanism.

Control over the generation of the AEN packets is achieved by control bits in the AEN Enable command. Each type of notification is optional and can be independently enabled by the Management Controller.

AENs are not acknowledged, and there is no protection against the possible loss of an AEN packet. Each defined event has its own AEN packet. Because the AEN packets are generated asynchronously by the Network Controller, they cannot implement some of the features of the other Control Packets. AEN packets leverage the general packet format of Control Packets.

- The originating Network Controller shall fill in the Channel ID (Ch. ID) field as defined in clause 6.1.9 in the AEN header to identify the source of notification.
- The IID field in an AEN shall be set to 0x00 to differentiate it from a response or command packet.

- The Network Controller shall copy the AEN MC ID field from the AEN Enable command into the MC ID field in every AEN sent to the Management Controller.

## 6.8 AEN handling in multiple medium implementations

Implementations that use NC-SI over physical interfaces other than RBT and enable Asynchronous Event Notifications (AEN) on those other media shall comply with the requirements in [DSP0261](#).

AENs that are enabled via RBT are specific to RBT-active operation and any AEN that is subsequently generated is only delivered over RBT and then only when RBT is active (maintained or restored operation).

AEN generation is suppressed and not cached when the media on which it was enabled is not active.

## 6.9 Error handling

### 6.9.1 Overview

This clause describes the error-handling methods that are supported over the NC-SI. Two types of error-handling methods are defined:

- Synchronous Error Handling
- Errors that trigger Asynchronous Entry into the Initial State

Synchronous Error Handling occurs when an Error (non-zero) Response/Reason Code is received in response to a command issued by the Management Controller. For information about response and reason codes, see clause 8.2.4.1.

Asynchronous Entry into the Initial State Error Handling occurs when the Network Controller asynchronously enters the Initial State because of an error condition that affects NC-SI configuration or a failure of a command that was already responded to. For more information, see clause 6.1.8.1.

### 6.9.2 Transport errors

#### 6.9.2.1 Dropped Control Packets

A Network Controller with an active interface shall drop Control Packets received on the NC-SI interface under the following conditions:

- The packet has an invalid Frame Check Sequence (FCS) value.
- Frame length does not meet [IEEE 802.3](#) requirements (except for OEM commands, where accepting larger packets may be allowed as a vendor-specific option).
- The packet checksum (if provided) is invalid.
- The NC-SI Channel ID value in the packet does not match the expected value.
- The Network Controller does not have resources available to accept the packet.
- The Network Controller receives a command packet with an incorrect header revision.
- Control Packets may also be dropped if an event that triggers Asynchronous Entry into the Initial State causes packets to be dropped during the transition..

#### 6.9.2.2 Pass-through packet errors

Handling of Pass-through packet errors, other than logging statistics, is out of scope of this specification.

### 6.9.3 Missing responses

#### 6.9.3.1 Overview

There are typical scenarios in which the Management Controller does not receive the response to a command:

- The Network Controller dropped the command and thus never sent the response.
- The response was dropped by the Management Controller (for example, because of a CRC error in the response packet).
- The Network Controller is in the process of being reset or is disabled.

The Management Controller can detect a missing response packet as the occurrence of an NC-SI command timeout event.

#### 6.9.3.2 Command timeout

The Management Controller may detect missing responses by implementing a command timeout interval. The timeout value chosen by the Management Controller shall not be less than Normal Execution Interval, T5. Upon detecting a timeout condition, the Management Controller should not make assumptions on the state of the unacknowledged command (for example, the command was dropped, or the response was dropped), but should retransmit (retry) the previous command using the same IID it used in the initial command.

The Management Controller should try a command at least three times before assuming an error condition in the Network Controller.

It is possible that a Network Controller could send a response to the original command at the same time a retried command is being delivered. Under this condition, the Management Controller could get more than one response to the same command. Thus, the Management Controller should be capable of determining that it has received a second instance of a previous response packet. Dropped commands may be detected by the Management Controller as a timeout event waiting for the response.

#### 6.9.3.3 Handling dropped commands or missing responses

To recover from dropped commands or missing responses, the Management Controller can retransmit the unacknowledged command packet using the same IID that it used for the initial command.

The Network Controller shall be capable of reprocessing retransmitted (retried) commands without error or undesirable side effects. The Network Controller can determine that the command has been retransmitted by verifying that the IID is unchanged from the previous command.

### 6.9.4 Detecting Pass-through traffic interruption

The Network Controller might asynchronously enter the Initial State because of a reset or other event. In this case, the Network Controller stops transmitting Pass-through traffic on the RXD lines. Similarly, Pass-through traffic sent to the Network Controller may be dropped. If the Management Controller is not in the state of sending or receiving Pass-through traffic, it may not notice this condition. Thus, the Management Controller should periodically issue a command to the Network Controller to test whether the Network Controller has entered the Initial State. How often this testing should be done is a choice of the Management Controller.

## 6.10 Support for additional network fabrics

### 6.10.1 FC support

NCs that support Fibre Channel connectivity can be inventoried, configured, and monitored. Fibre Channel-specific link speed, link status, boot configuration and statistics commands are provided. Fibre Channel over Ethernet (FCoE) support is also defined for Ethernet NCs that support it.

#### InfiniBand Support

NCs that support InfiniBand connectivity can be inventoried, configured, and monitored. InfiniBand-specific link speed, link status and statistics commands are provided.

## 6.11 PLDM and SPDM transport

NC-SI over RBT can be used to transport SPDM or PLDM messages. This transport supports the following modes:

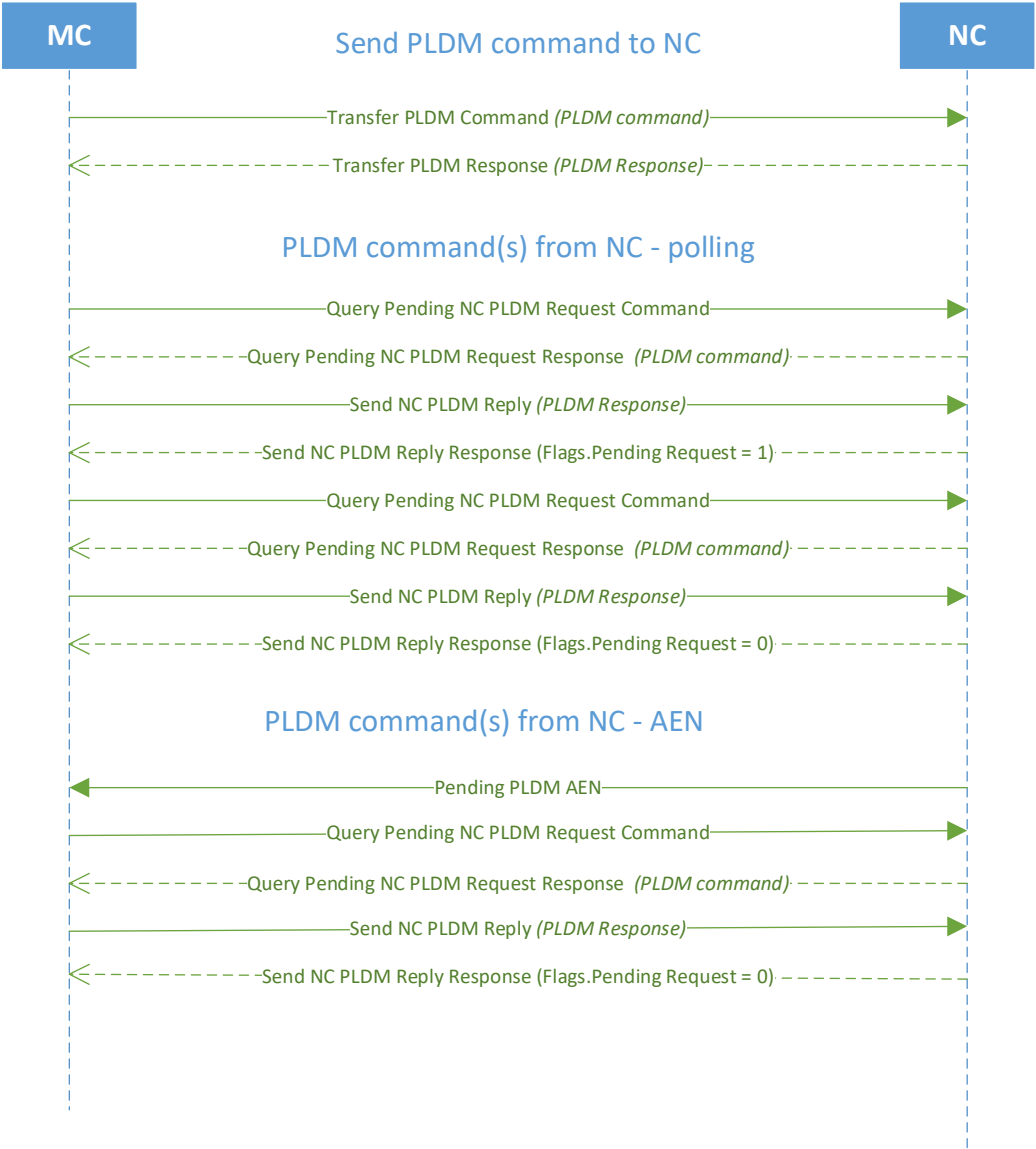

- MC sends PLDM and/or SPDM commands to the NC.
- MC polls the NC for PLDM and/or SPDM commands originating at the NC.
- The NC indicates through an AEN that a PLDM/SPDM command is available for retrieval.

The following commands are used to implement an RBT binding for these messages:

**Table 4 – Commands for RBT binding**

Command	PLDM	SPDM
Send command from MC	PLDM Request	Transfer SPDM
Poll for NC command	Query Pending NC PLDM Request	Query Pending NC SPDM Request
Respond to NC command	Send NC PLDM Reply	Send NC SPDM Reply
AEN	Pending PLDM AEN	Pending SPDM AEN

The PLDM and SPDM command flows are described in the UML diagrams below.

1778

## 7 Arbitration in configurations with multiple Network Controller packages

### 7.1 Overview

This clause applies to NC-SI over RBT only.

More than one Network Controller package on a RBT interface can be enabled for transmitting packets to the Management Controller. This specification defines two mechanisms to accomplish Network Controller package arbitration operations. One mechanism uses software commands provided by the Network Controller for the Management Controller to control whose turn it is to transmit traffic. The other mechanism uses hardware arbitration to share the single RBT bus. Implementations are required to support command-based Device Selection operation; the hardware arbitration method is typically desired but is optional.

### 7.2 Multi-controller RBT

Figure 10 is a simplified block diagram of the Sideband Interface being used in a multi-drop configuration. The RMII (upon which NC-SI RBT is based) was originally designed for use as a point-to-point interconnect. Accordingly, only one party can transmit data onto the bus at any given time. There is no arbitration protocol intrinsic in the RMII specification to support managing multiple transmitters.

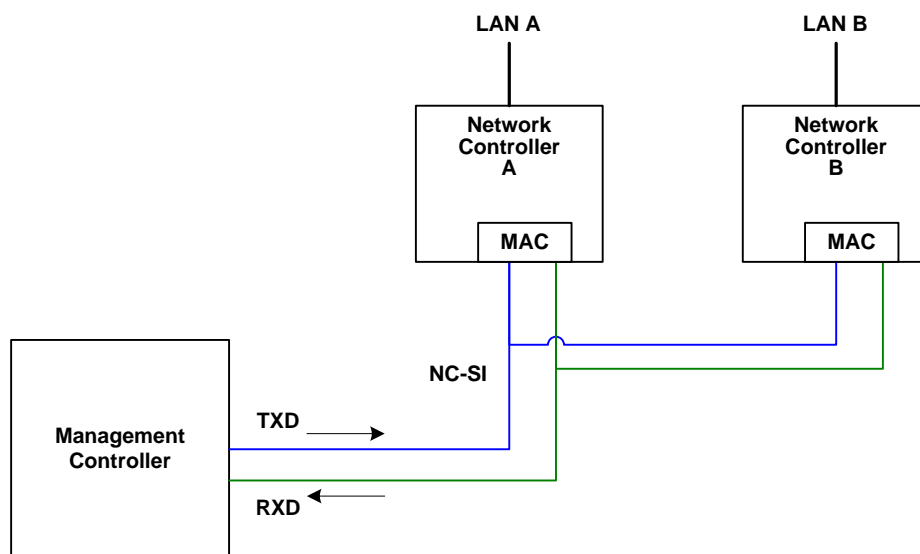

Figure 10 – Basic multi-drop block diagram

However, it is possible for multiple Network Controllers on the interface to be able to simultaneously receive traffic from the Management Controller that is being transmitted on the RBT TXD lines. The Network Controllers can receive commands from the Management Controller without having to arbitrate for the bus. This facilitates the Management Controller in delivering commands for setup and configuration of arbitration.

Arbitration allows multiple Network Controller packages that are attached to the interface to be enabled to share the RXD lines to deliver packets to the Management Controller.

1804 This operation is summarized as follows:

- 1805 • Only one Network Controller at a time can transmit packets on the RXD lines of the interface.
- 1806 • Network Controllers can accept commands for configuring and controlling arbitration for the
- 1807 RXD lines.

## 1808 7.3 Hardware arbitration

1809 To prevent two or more NC-SI packages from transmitting at the same time, a hardware-based arbitration  
1810 scheme was devised to allow only one Network Controller package to drive the RX lines of the shared  
1811 interface at any given time. This scheme uses a mechanism of passing messages (opcodes) between  
1812 Network Controller packages to coordinate when a controller is allowed to transmit through the RBT  
1813 interface.

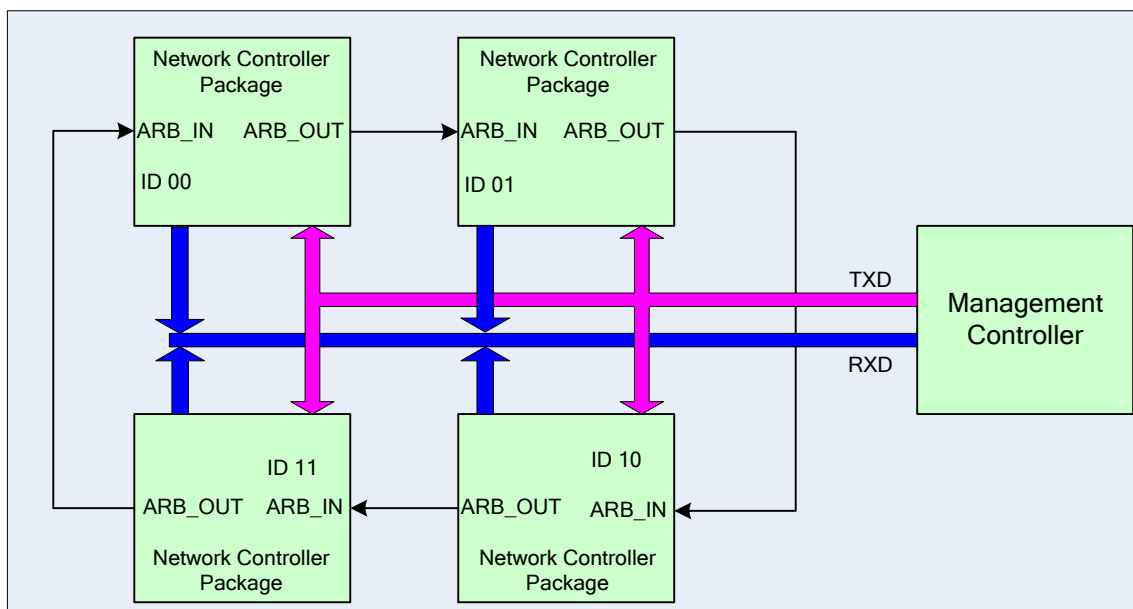

### 1814 7.3.1 General

1815 Three conceptual modes of hardware arbitration exist: arbitration master assignment, normal operation,  
1816 and bypass. After a package is initialized and has its Channel IDs assigned, it enters the arbitration  
1817 master assignment mode. This mode assigns one package the role of an Arbitration Master  
1818 (ARB\_Master) that is responsible for initially generating a TOKEN opcode that is required for the normal  
1819 operating mode. In the normal operating mode, the TOKEN opcode is passed from one package to the  
1820 next in the ring. The package is allowed to use the shared RXD signals and transmit if the package has  
1821 received the TOKEN opcode and has a packet to send.

1822 Bypass mode allows hardware arbitration opcodes to pass through a Network Controller package before  
1823 it is initialized. Bypass mode shall be in effect while hardware arbitration is disabled. Bypass mode shall  
1824 be exited, and arbitration master assignment mode shall be entered when the hardware arbitration  
1825 becomes enabled or re-enabled.

1826 Hardware-based arbitration requires two additional pins (ARB\_IN and ARB\_OUT) on the Network  
1827 Controller. The ARB\_OUT pin of one package is connected to the ARB\_IN pin of the next package to  
1828 form a ring configuration, as illustrated in Figure 11. The timing requirements for hardware arbitration are  
1829 designed to accommodate a maximum of four Network Controller packages. If the implementation  
1830 consists of a single Network Controller package, the ARB\_OUT pin may be connected to the ARB\_IN pin  
1831 on the same package, or may be left disconnected, in which case hardware arbitration should be disabled  
1832 by using the Select Package command. This specification optionally supports reporting of Hardware  
1833 arbitration implementation status and hardware arbitration status using the **Get Capabilities** command.

1834

**Figure 11 – Multiple Network Controllers in a ring format**

Each Network Controller package sends out pulses on the ARB\_OUT pin to create a series of symbols that form opcodes (commands) between Network Controllers. Each pulse is one clock wide and synchronized to REF\_CLK. The hardware arbitration data bits follow the same timing specifications used for the TXD and RXD data bits (see clause 10.2.7). The pulses are di-bit encoded to ensure that symbols are correctly decoded. The symbols have the values shown in Table 5.

While clause 7.3.2.1 allows for opcode to be truncated, it is recommended that the transmission of current opcode on ARB\_OUT be completed if the HW arbitration mode is changed in the middle of an opcode transfer (or in the middle of a symbol).

**Table 5 – Hardware arbitration di-bit encoding**

Symbol Name	Encoded Value
E <sub>sync</sub>	11b
E <sub>zero</sub>	00b
E <sub>one</sub>	01b
Illegal symbol	10b

### 7.3.2 Hardware arbitration opcodes

The hardware-based arbitration feature has five defined opcodes: IDLE, TOKEN, FLUSH, XON, and XOFF. Each opcode starts with an E<sub>sync</sub> symbol and is followed by either E<sub>one</sub> or E<sub>zero</sub> symbols. The legal opcodes are listed in Table 6.

Table 6 – Hardware arbitration opcode format

Opcode	Format
IDLE	$E_{sync} E_{zero} E_{zero} (110000b)$
TOKEN	$E_{sync} E_{one} E_{zero} (110100b)$
FLUSH	$E_{sync} E_{one} E_{one} E_{zero} E(Package\_ID[2:0]) E_{zero} (11010100xxxxxx00b)$
XOFF	$E_{sync} E_{zero} E_{one} E_{zero} E_{zero} E_{zero} (1100010000000b)$
XON	$E_{sync} E_{zero} E_{one} E_{one} E_{zero} E(Package\_ID[2:0]) E_{zero} (1100010100uuuuuu00b)$

### 7.3.2.1 Detecting truncated opcodes

A truncated opcode is detected when the number of clocks between  $E_{sync}$ s is less than the number of bits required for the opcode. Note that any additional bits clocked in after a legitimate opcode is detected do not indicate an error condition and are ignored until the next  $E_{sync}$ .

### 7.3.2.2 Handling truncated or illegal opcodes

When a Network Controller receives a truncated or illegal opcode, it should discard it.

### 7.3.2.3 Relationship of opcodes processing and driving the RX data lines

A Network Controller package shall take no more than T9 REF\_CLK times after receiving the last bit of the opcode to decode the incoming opcode and start generating the outgoing opcode. This time limit allows for decoding and processing of the incoming opcode under the condition that an outgoing opcode transmission is already in progress.

A package that has received a TOKEN and has packet data to transmit shall turn on its buffer and begin transmitting the packet data within T11 REF\_CLK times of receiving the TOKEN, as illustrated in Figure 12. The package shall disable the RXD buffers before the last clock of the transmitted TOKEN.

Figure 12 – Opcode to RXD relationship

### 7.3.3 Opcode operations

#### 7.3.3.1 TOKEN opcode

When a TOKEN opcode is received, the Network Controller package may drive the RXD signals to send only one of the following items: a Pass-through packet, a command response, or an AEN. One [IEEE 802.3](#) PAUSE frame (XON or XOFF) may also be sent either before or after one of the previous packets, or on its own. While the Network Controller package is transmitting the data on the RXD signals of the interface, it shall generate IDLE opcodes on its ARB\_OUT pin. Once a package completes its transmission, if any, it shall generate and send the TOKEN on its ARB\_OUT pin.

#### 7.3.3.2 IDLE opcode

A package that has no other opcode to send shall continuously generate IDLE opcodes. Typically, a received IDLE opcode indicates that the TOKEN is currently at another package in the ring. This opcode is also used in the ARB\_Master assignment process (for details, see clause 7.3.5). An Idle opcode typically will also be generated when the package is transmitting on RBT

#### 7.3.3.3 FLUSH opcode

A FLUSH opcode is used to establish an Arbitration Master for the ring when the package enters the Package Ready state or when the TOKEN is not received within the specified timeout, T8. This opcode is further explained in clause 7.3.5.

If the package receives a FLUSH opcode while it is in the middle of transmitting a packet onto NC-SI, it shall generate IDLE opcodes until the transmission is complete and then process the FLUSH opcode as described.

#### 7.3.3.4 Flow Control opcodes

The XON and XOFF opcodes are used to manage the generation of [IEEE 802.3](#) PAUSE frames on the RBT interface. If the Network Controller supports flow control and flow control is enabled, the XOFF and XON opcodes behave as described in this clause. If the Network Controller does not support flow control or if flow control is not enabled, the Network Controller shall pass the opcodes to the next package.

There may be a configuration where some NCs support flow control and others do not. In this configuration, an NC sending an XOFF opcode may see the XOFF packet emission delayed by two or more full size Pass-through packets, one for each package not supporting XOFF when it gets the token, and one for the next package supporting XOFF before sending the XOFF packet. The NC is not required to provide buffering to prevent packet loss in this configuration. No drop behavior should be expected by an MC only if all NCs have flow control enabled.

NOTE: There is a maximum amount of time that the Network Controller is allowed to maintain a PAUSE. For more information, see clause 8.5.41.

##### 7.3.3.4.1 XOFF opcode

A Network Controller package that becomes congested while receiving packets from the NC-SI shall perform the following actions:

- If it does not have a TOKEN, it sends the XOFF opcode to the next package.

NOTE: If it has the TOKEN and has not previously sent an XOFF frame for this instance of congestion, it shall send a single XOFF frame (PAUSE frame with a pause time of 0xFFFF) and will not generate an XOFF opcode.

- A package may also regenerate an XOFF frame or opcode if it is still congested and determines that the present PAUSE frame is about to expire.

1909 When a package on the ring receives an XOFF opcode, it shall perform one of the following actions:

- 1910 • If it does not have a TOKEN opcode, it passes the XOFF opcode to the next package in the
- 1911 ring.
- 1912 • If it has the TOKEN, it shall send an XOFF frame (PAUSE frame with a pause time of 0xFFFF)
- 1913 and will not regenerate the XOFF opcode. If it receives another XOFF opcode while sending the
- 1914 XOFF frame or a regular network packet, it discards the received XOFF opcode.

#### 1915 7.3.3.4.2 XON opcode

1916 XON frames (PAUSE frame with a pause time of 0x0000) are used to signal to the Management  
 1917 Controller that the Network Controller packages are no longer congested and that normal traffic flow can  
 1918 resume. XON opcodes are used between the packages to coordinate XON frame generation. The  
 1919 package ID is included in this opcode to provide a mechanism to verify that every package is not  
 1920 congested before sending an XON frame to the Management Controller.

1921 The XON opcode behaves as follows:

- 1922 • When a package is no longer congested, it generates an XON opcode with its own Package ID.  
 1923 This puts the package into the 'waiting for its own XON' state.
- 1924 • A package that receives the XON opcode takes one of the following actions:
  - 1925 – If it is congested, it replaces the received XON opcode with the IDLE opcode. This action  
 1926 causes the XON opcode to be discarded. Eventually, the congested package generates its  
 1927 own XON opcode when it exits the congested state.
  - 1928 – If the package is not congested and is not waiting for the XON opcode with own Package  
 1929 ID, it forwards the received XON opcode to the next package in the ring.
  - 1930 – If the received XON opcode contains the package's own Package ID, the opcode should  
 1931 be discarded.
  - 1932 – If the package is not congested and is waiting for its own XON opcode, it performs one of  
 1933 the following actions:
    - 1934 • If it receives an XON opcode with a Package ID that is higher than its own, it replaces  
 1935 the XON opcode with its own Package ID.
    - 1936 • If it receives an XON opcode with a Package ID lower than its own, it passes that  
 1937 XON opcode to the next package and it exits the 'waiting for its own XON' state.
    - 1938 • If it receives an XON opcode with the Package ID equal to its own, it sends an XON  
 1939 frame on the NC-SI when it receives the TOKEN opcode and exits the 'waiting for its  
 1940 own XON' state.

1941 NOTE: More than one XON opcode with the same Package ID can be received while  
 1942 waiting for the TOKEN and while sending the XON frame. These additional XON  
 1943 opcodes should be discarded.

- 1944 • If a package originates an XON opcode but receives an XOFF opcode, it terminates its XON  
 1945 request so that it does not output an XON frame when it receives the TOKEN.

1946 NOTE: This behavior is not likely to occur because the Management Controller will be in the  
 1947 Pause state at this point.

- 1948 • A package that generated an XON opcode may receive its own XON opcode back while it has  
 1949 the TOKEN opcode. In this case, it may send a regular packet (Pass-through, command  
 1950 response, or AEN) to the Management Controller (if it has one to send), an XON frame, or both.

### 7.3.4 Bypass mode

When the Network Controller package is in bypass mode, data received on the ARB\_IN pin is redirected to the ARB\_OUT pin within the specified clock delay. This way, arbitration can continue between other devices in the ring.

A package in bypass mode shall take no more than T10 REF\_CLK times to forward data from the ARB\_IN pin to the ARB\_OUT pin. The transition in and out of bypass mode may result in a truncated opcode.

A Network Controller package enters bypass mode immediately upon power up and transitions out of this mode after the Network Controller completes its startup/initialization sequence.

### 7.3.5 Hardware arbitration startup

Hardware arbitration startup works as follows:

- 1) All the packages shall be in bypass mode within T<sub>pwrz</sub> seconds of NC-SI power up.
- 2) As each package is initialized, it shall continuously generate FLUSH opcodes with its own Package ID.
- 3) The package then participates in the ARB\_MSTR assignment process described in the following clause.

### 7.3.6 ARB\_MSTR assignment

ARB\_MSTR assignment works as follows:

- 1) When a package receives a FLUSH opcode with a Package ID numerically smaller than its own, it shall forward on the received FLUSH opcode. If the received FLUSH opcode's Package ID is numerically larger than the local Package ID, the package shall continue to send its FLUSH opcode with its own Package ID. When a package receives a FLUSH opcode with its own Package ID, it becomes the master of the ring (ARB\_MSTR).
- 2) The ARB\_MSTR shall then send out IDLE opcodes until it receives an IDLE opcode.
- 3) Upon receiving the IDLE opcode, the ARB\_MSTR shall be considered to be in possession of the TOKEN opcode (see clause 7.3.3.1).
- 4) If the package receives a FLUSH opcode while it is in the middle of transmitting a packet onto NC-SI, it shall generate IDLE opcodes until the transmission is complete and then process the FLUSH opcode as described.

### 7.3.7 Token timeout mechanism

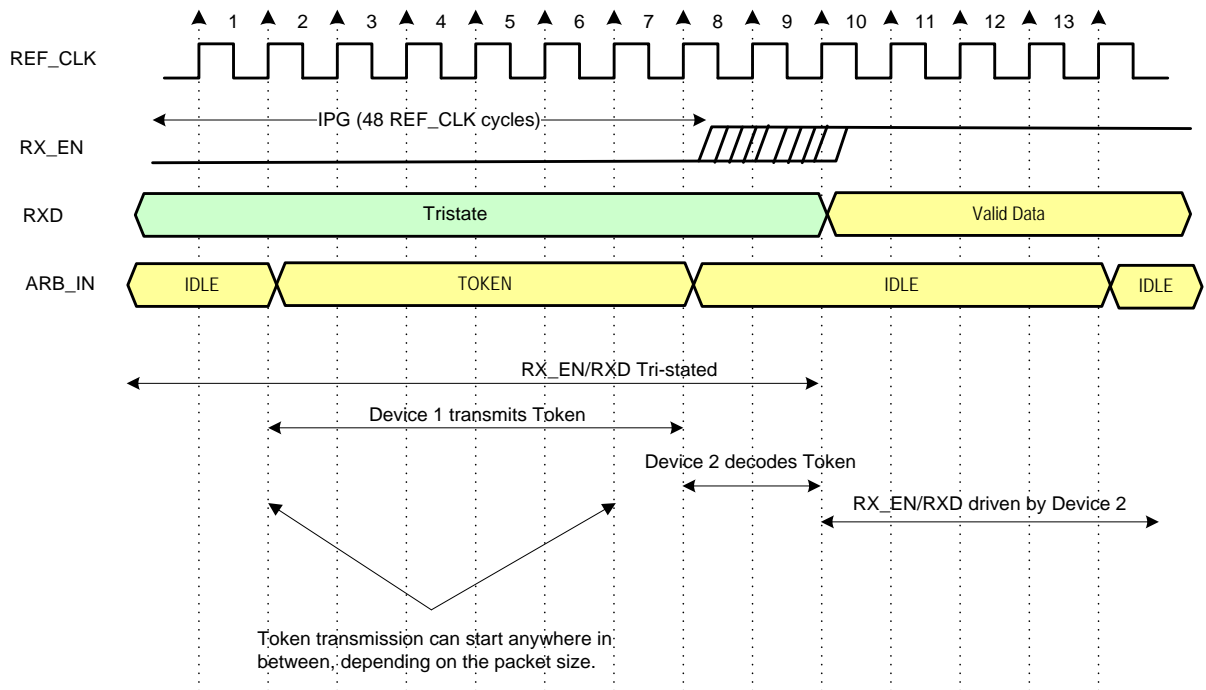

Each Network Controller package that supports hardware-based arbitration control shall implement a timeout mechanism in case the TOKEN opcode is not received. When a package has a packet to send, it starts its timer. If it does not receive a TOKEN prior to the TOKEN timeout, the package shall send a FLUSH opcode. This restarts the arbitration process.

The timer may be programmable depending on the number of packages in the ring. The timeout value is designed to accommodate up to four packages, each sending the largest packet (1536 bytes) plus possible XON or XOFF frame transmission and opcode processing time. The timeout shall be no fewer than T8 cycles of the REF\_CLK.

### 7.3.8 Timing considerations

The ARB\_OUT and ARB\_IN pins shall follow the timing specifications outlined in clause 10.

To improve the efficiency of the multi-drop NC-SI, TOKEN opcode generation may overlap the Inter Packet Gap (IPG) defined by the [802.3](#) specification, as shown in Figure 13. The TOKEN opcode shall be sent no earlier than the last T13 REF\_CLK cycles of the IPG.

**Figure 13 – Example TOKEN to transmit relationship**

### 7.3.9 Example hardware arbitration state machine

The state machine diagram shown in Figure 14 is provided as a guideline to help illustrate the startup process and opcode operations described in the preceding clauses.

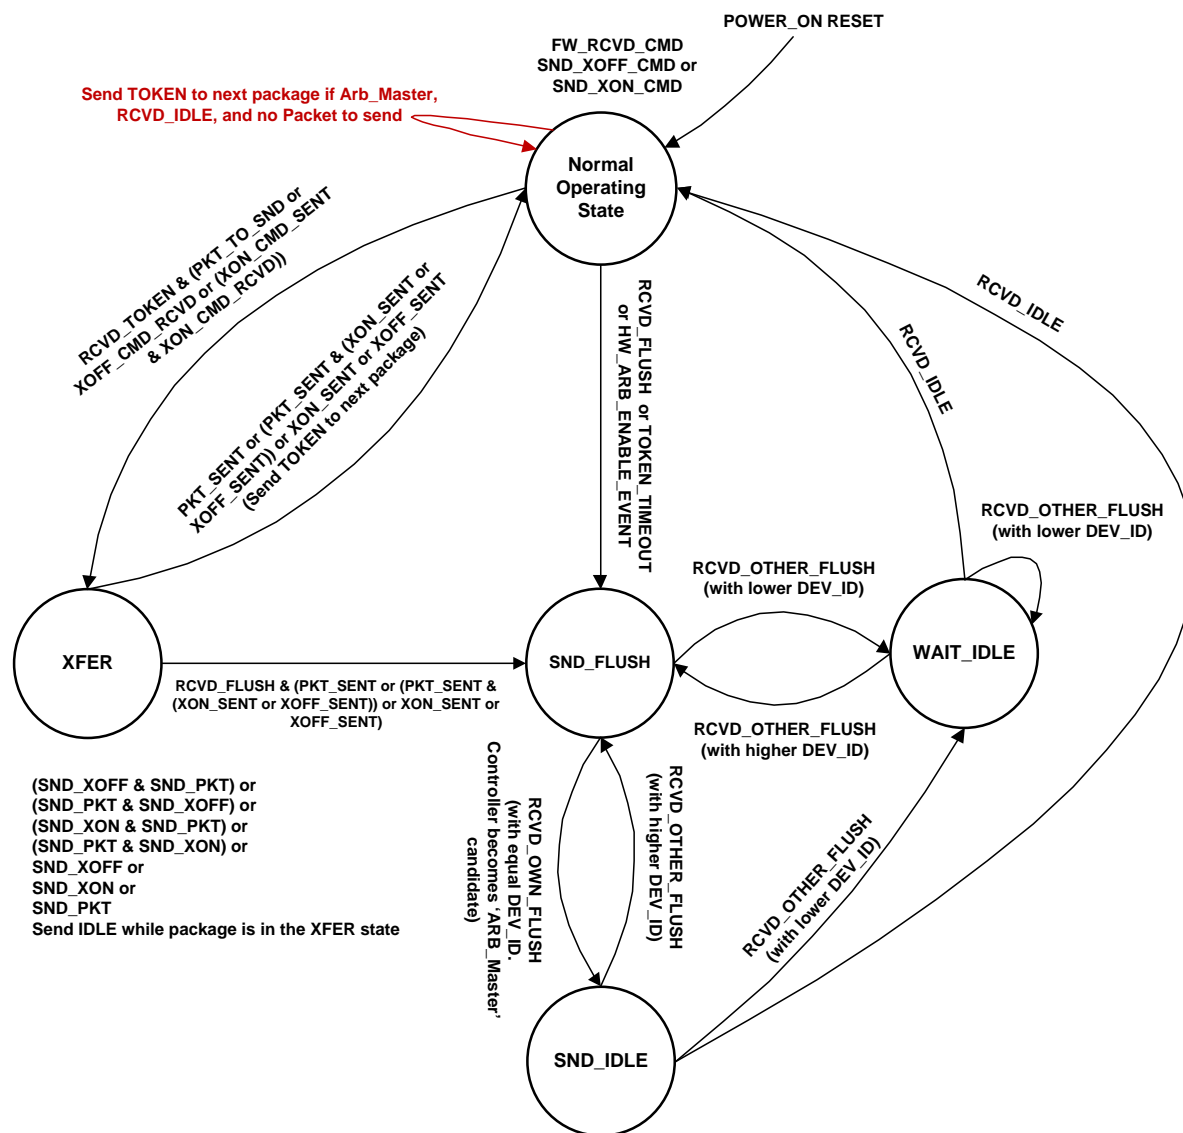

Figure 14 – Hardware arbitration state machine

The states and events shown in Figure 14 are described in Table 7 and Table 8, respectively.

2002

Table 7 – Hardware arbitration states

State	Action
Normal Operating State	<p>This state is the normal operating state for hardware arbitration. The following actions happen in this state:</p> <ul style="list-style-type: none"> <li>• FW_RCVD_CMD: Forward received command. As opcodes are received and acted upon, the resulting opcode is sent to the next package. For example, the TOKEN opcode is received, and no packet data is available to send, so the TOKEN opcode is sent to the next package in the ring.</li> <li>• SND_XOFF_CMD: Send the XOFF opcode to the next package. This action happens when the specific conditions are met as described in clause 7.3.3.</li> <li>• SND_XON_CMD: Send the XON opcode to the next package. This action happens when the specific conditions are met as described in clause 7.3.3.</li> <li>• If the Network Controller is ARB_Master, it generates the TOKEN opcode upon receiving an IDLE opcode at the end of the FLUSH process.</li> <li>• The RXD lines will be in a high-impedance condition in this state.</li> </ul>
XFER	<p>In this state, data is sent on the RXD lines. This data will be a Pass-through packet, response packet, XON (Pause Off) packet, XOFF (Pause On) packet, or AEN. (An XON or XOFF packet can be sent in addition to a Pass-through packet, response packet, or AEN.) IDLE opcodes are sent to the next package while the device is in the XFER state.</p> <p>The following actions happen in this state:</p> <ul style="list-style-type: none"> <li>• SND_XON: Transmit an XON frame (Pause Off) to the Management Controller.</li> <li>• SND_XOFF: Transmit an XOFF frame (Pause On) to the Management Controller.</li> <li>• SND_PKT: Transmit a Pass-through packet, response packet, or AEN to the Management Controller.</li> <li>• The TOKEN opcode is sent to the next package upon completion of the transfer.</li> </ul>
SND_FLUSH	<p>This state is the entry point for determining the ARB_Master among the packages. In this state, the FLUSH opcode is continuously sent. This state is exited upon receiving a FLUSH opcode that has a DEV_ID that is equal to or lower than the package's own DEV_ID.</p>
SND_IDLE	<p>This is the final state for determining the ARB_Master, entered when a device's own FLUSH opcode is received. In this state, the IDLE opcode is continuously sent.</p>
WAIT_IDLE	<p>This state is entered when a FLUSH command is received from another package with a lower Device ID. When an IDLE opcode is received, the ARB_Master has been determined and the device transitions to the Normal Operating State.</p>

2003

Table 8 – Hardware arbitration events

Event	Description
RCVD_TOKEN	A TOKEN opcode was received, or the arbitration was just completed and won by this package.
RCVD_IDLE	An IDLE opcode was received.
XOFF_SENT	The Pause On frame was sent on the RXD interface.
XON_SENT	The Pause Off frame was sent on the RXD interface.
PKT_TO_SND	The Network Controller package has a Pass-through packet, command response packet, XON (Pause Off) frame, XOFF (Pause On) frame, or AEN to send.
XON_CMD_RCVD	A package received an XON opcode with its own Package ID.
XOFF_CMD_RCVD	An XOFF opcode was received.
XON_CMD_SENT	A package sent an XON opcode with its own Package ID.
RCVD_FLUSH	A FLUSH opcode was received.
TOKEN_TIMEOUT	The timeout limit expired while waiting for a TOKEN opcode.
HW_ARB_ENABLE_EVENT	This event begins ARB_MSTR assignment. This event occurs just after the Network Controller package initializes or when hardware arbitration is re-enabled through the Select Package command.
RCVD_OTHER_FLUSH	A package received a FLUSH opcode with a Package ID other than its own.
RCVD_OWN_FLUSH	A package received a FLUSH opcode with a Package ID equal to its own.

2004

## 7.4 Command-based arbitration

2005

If hardware arbitration is not being used, the **Select Package** and **Deselect Package** commands shall be used to control which Network Controller package can transmit on the RXD lines. Because only one

2006

Network Controller package is allowed to transmit on the RXD lines, the Management Controller shall

2007

only have one package in the selected state at any given time. For more information, see clauses 8.5.5

2008

and 8.5.7.

2009

2010

## 8 Packet definitions

### 8.1 NC-SI packet encapsulation

The RBT interface is an Ethernet interface adhering to the standard [IEEE 802.3](#) Ethernet frame format. Whether or not the Network Controller accepts runt packets is unspecified.

As shown in Figure 15, this L2, or data link layer, frame format encapsulates all NC-SI packets, including Pass-through, command, and response packets, as the L2 frame payload data by adding a 14-byte header to the front of the data and appending a 4-byte Frame Check Sequence (FCS) to the end.

NC-SI Control Packets shall not include any VLAN tags. NC-SI Pass-through packets may include an 802.1Q VLAN tag.

**Figure 15 – Ethernet frame encapsulation of NC-SI packet data without VLAN tag**

#### 8.1.1 Ethernet frame header

The Management Controller shall format the 14-byte Ethernet frame header so that when it is received, it shall be formatted in the big-endian byte order shown in Table 9.

Channels shall accept Pass-through packets that meet the [IEEE 802.3](#) frame requirements.

**Table 9 – Ethernet Header Format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..03	DA <sub>5</sub> = 0xFF	DA <sub>4</sub> = 0xFF	DA <sub>3</sub> = 0xFF	DA <sub>2</sub> = 0xFF
04..07	DA <sub>1</sub> = 0xFF	DA <sub>0</sub> = 0xFF	SA <sub>5</sub>	SA <sub>4</sub>
08..11	SA <sub>3</sub>	SA <sub>2</sub>	SA <sub>1</sub>	SA <sub>0</sub>
12..13	Ethertype = 0x88F8 (DMTF NC-SI)			

##### 8.1.1.1 Destination Address (DA)

Bytes 0–5 of the header represent bytes 5–0 of the Ethernet Destination Address field of an L2 header.

The channel is not assigned a specific MAC address and the contents of this field are not interpreted as a MAC address by the Management Controller or the Network Controller. However, the DA field in all NC-SI Control Packets shall be set to the broadcast address (FF:FF:FF:FF:FF:FF) for consistency.

If the Network Controller receives a Control Packet with a Destination Address other than FF:FF:FF:FF:FF:FF, the Network Controller may elect to accept the packet, drop it, or return a response packet with an error response/reason code.

### 8.1.1.2 Source Address (SA)

Bytes 6–11 of the header represent bytes 5–0 of the Ethernet Source MAC Address field of the Ethernet header. The contents of this field may be set to any value. The Network Controller should use FF:FF:FF:FF:FF:FF as the source address for NC-SI Control Packets that it generates.

### 8.1.1.3 Ethertype

The final two bytes of the header, bytes 12..13, represent bytes 1..0 of the Ethertype field of the Ethernet header. For NC-SI Control Packets, this field shall be set to a fixed value of 0x88F8 as assigned to NC-SI by the IEEE. This value allows NC-SI Control Packets to be differentiated from other packets in the overall packet stream.

## 8.1.2 Frame Check Sequence

The Frame Check Sequence (FCS) shall be added at the end of the frame to provide detection of corruption of the frame. Any frame with an invalid FCS shall be discarded.

## 8.1.3 Data length

NC-SI Commands, Responses, and AENs do not carry any VLAN tag. NC-SI Commands, Responses and AENs shall have a payload data length between 46 and 1500 octets (bytes). This complies with the 802.3 specification. This means that the length of Ethernet frame shown in Figure 15 is between 64 octets (for a payload of 46 octets) and 1518 octets (for a payload with 1500 octets).

Pass-through packets also follow the 802.3 specification. The maximum payload size is 1500 octets; the minimum payload size shall be 42 octets when 802.1Q (VLAN) tag is present and 46 octets when the 802.1Q tag is not present. The Layer-2 Ethernet frame for an 802.1Q tagged frame shall be between 64 octets (for a payload of 42 octets) and 1522 octets (for a payload with 1500 octets). For Pass-through packets that are not 802.1Q tagged, the minimum Layer-2 Ethernet frame size is 64 octets (for a payload of 46 octets) and the maximum Layer-2 Ethernet frame size is 1518 octets (for a payload with 1500 octets).

## 8.2 Control Packet data structure

Each NC-SI Control Packet is made up of a 16-byte packet header and a payload section whose length is specific to the packet type.

### 8.2.1 Control Packet header

The 16-byte Control Packet header is used in command, response, and AEN packets, and contains data values intended to allow the packet to be identified, validated, and processed. The packet header is in big-endian byte order, as shown in Table 10.

**Table 10 – Control Packet header format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..03	MC ID	Header Revision	Reserved	IID

Bytes	Bits			
	31..24	23..16	15..08	07..00
04..07	Control Packet Type	Ch. ID	Flags	Payload Length
08..11	Reserved			
12..15	Reserved			

### 8.2.1.1 Management Controller ID

In Control Packets, this 1-byte field identifies the Management Controller issuing the packet. For this version of the specification, Management Controllers should set this field to 0x00 (zero). This implies that only one management controller is supported for accessing the NC via NC-SI at any given time, Network Controllers responding to command packets should copy the Management Controller ID field from the command packet header into the response packet header. For AEN packets, this field should be copied from the parameter that was set using the AEN Enable command.

### 8.2.1.2 Header revision

This 1-byte field identifies the version of the Control Packet header in use by the sender. For this version of the specification, the header revision is 0x01.

### 8.2.1.3 Instance ID (IID)

This 1-byte field contains the IID of the command and associated response. The Network Controller can use it to differentiate retried commands from new instances of commands. The Management Controller can use this value to match a received response to the previously sent command. For more information, see clause 6.2.2.2.

### 8.2.1.4 Control Packet type

This 1-byte field contains the Identifier that is used to identify specific commands and responses, and to differentiate AENs from responses. Each NC-SI command is assigned a unique 7-bit command type value in the range 0x00 . . 0x60. The proper response type for each command type is formed by setting the most significant bit (bit 7) in the original 1-byte command value. This allows for a one-to-one correspondence between 96 unique response types and 96 unique command types.

### 8.2.1.5 Channel ID

This 1-byte field contains the Network Controller Channel Identifier. The Management Controller shall set this value to specify the package and internal channel ID for which the command is intended.

In a multi-drop configuration, all commands are received by all NC-SI Network Controllers present in the configuration. The Channel ID is used by each receiving Network Controller to determine if it is the intended recipient of the command. In Responses and AENs, this field carries the Channel ID I from which the response or AEN was issued.

### 8.2.1.6 Payload length

This 12-bit field contains the length, in bytes, of any payload data present in the command or response frame following the NC-SI packet header. This value does not include the length of the NC-SI Control Packet Header, the checksum value, or any padding that might be present.

### 2101 8.2.1.7 Flags

2102 Bit 0: Poll Indication: If this bit is set, it indicates that this command instance is polling on a previously sent  
 2103 command that was responded with a “Delayed Response” response code. This bit is relevant only for  
 2104 commands and not for responses or AENs.

2105 Bits 3:1: Reserved

### 2106 8.2.1.8 Reserved

2107 These fields are reserved for future use and should be written as zeros and ignored when read.

## 2108 8.2.2 Control Packet payload

2109 The NC-SI packet payload may contain zero or more defined data values depending on whether the  
 2110 packet is a command or response packet, and on the specific type. The NC-SI packet payload is always  
 2111 formatted in big-endian byte order, as shown in Table 11.

2112 **Table 11 – Generic example of Control Packet payload**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..03	Data0 <sub>3</sub>	Data0 <sub>2</sub>	Data0 <sub>1</sub>	Data0 <sub>0</sub>
04..07	Data1 <sub>7</sub>	Data1 <sub>6</sub>	Data1 <sub>5</sub>	Data1 <sub>4</sub>
08..11	Data1 <sub>3</sub>	Data1 <sub>2</sub>	Data1 <sub>1</sub>	Data1 <sub>0</sub>
..				
...	DataN-1 <sub>4</sub>	DataN-1 <sub>3</sub>	DataN-1 <sub>2</sub>	DataN-1 <sub>1</sub>
...	DataN-1 <sub>0</sub>	Payload Pad (as required)		
...	Checksum			
...	Ethernet Packet Pad (as required)			

### 2113 8.2.2.1 Data

2114 As shown in Table 11, the bytes following the NC-SI packet header may contain payload data fields of  
 2115 varying sizes, and which may be aligned or require padding. In the case where data is defined in the  
 2116 payload, all data-field byte layouts (Data0–Data1) shall use big-endian byte ordering with the most  
 2117 significant byte of the field in the lowest addressed byte position (that is, coming first).

### 2118 8.2.2.2 Payload pad

2119 If the payload is present and does not end on a 32-bit boundary, one to three padding bytes equal to  
 2120 0x00 shall be present to align the checksum field to a 32-bit boundary.

### 2121 8.2.2.3 Checksum

2122 This 4-byte field contains the 32-bit checksum compensation value that may be included in each  
 2123 command and response packet by the sender of the packet. When it is implemented, the checksum  
 2124 compensation shall be computed as the 2’s complement of the checksum, which shall be computed as  
 2125 the 32-bit unsigned sum of the NC-SI packet header and NC-SI packet payload interpreted as a series of  
 2126 16-bit unsigned integer values. A packet receiver supporting packet checksum verification shall use the  
 2127 checksum compensation value to verify packet data integrity by computing the 32-bit checksum described  
 2128 above, adding to it the checksum compensation value from the packet, and verifying that the result is 0.

2129 Verification of non-zero NC-SI packet checksum values is optional. An implementation may elect to  
 2130 generate the checksums and may elect to verify checksums that it receives. The checksum field is  
 2131 generated and handled according to the following rules:

- 2132       • A checksum field value of all zeros specifies that a header checksum is not being provided for  
 2133       the NC-SI Control Packet, and that the checksum field value shall be ignored when processing  
 2134       the packet.
- 2135       • If the originator of an NC-SI Control Packet is not generating a checksum, the originator shall  
 2136       use a value of all zeros for the header checksum field.
- 2137       • If a non-zero checksum field is generated for an NC-SI Control Packet, that header checksum  
 2138       field value shall be calculated using the specified algorithm.
- 2139       • All receivers of NC-SI Control Packets shall accept packets with all zeros as the checksum  
 2140       value (provided that other fields and the CRC are correct).
- 2141       • The receiver of an NC-SI Control Packet may reject (silently discard) a packet that has an  
 2142       incorrect non-zero checksum.
- 2143       • The receiver of an NC-SI Control Packet may ignore any non-zero checksums that it receives  
 2144       and accept the packet, even if the checksum value is incorrect (that is, an implementation is not  
 2145       required to verify the checksum field).
- 2146       • A controller that generates checksums is not required to verify checksums that it receives.
- 2147       • A controller that verifies checksums is not required to generate checksums for NC-SI Control  
 2148       Packets that it originates.

#### 2149 8.2.2.4 Ethernet packet pad

2150 Per [IEEE 802.3](#), all Ethernet frames shall be at least 64 bytes in length, from the DA through and  
 2151 including FCS. For NC-SI packets, this requirement applies to the Ethernet header and payload, which  
 2152 includes the NC-SI Control Packet header and payload. Most NC-SI Control Packets are less than the  
 2153 minimum Ethernet frame payload size of 46 bytes in length and require padding to comply with  
 2154 [IEEE 802.3](#).

#### 2155 8.2.3 Command packet payload

2156 Command packets have no common fixed payload format.

#### 2157 8.2.4 Response packet payload

2158 Unlike command packets that do not necessarily contain payload data, all response packets carry at least  
 2159 a 4-byte payload. This default payload carries the response codes and reason codes (described in clause  
 2160 8.2.4.1) that provide status on the outcome of processing the originating command packet and is present  
 2161 in all response packet payload definitions.

2162 The default payload occupies bytes 00..03 of the response packet payload, with any additional  
 2163 response-packet-specific payload defined to follow starting on the next word. All response packet payload  
 2164 fields are defined with big-endian byte ordering, as shown in Table 12.

2165 **Table 12 – Generic example of Response packet payload format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..03	Response Code		Reason Code	

..	...	...	...	...
...	DataN-1 <sub>4</sub>	DataN-1 <sub>3</sub>	DataN-1 <sub>2</sub>	DataN-1 <sub>1</sub>
...	DataN-1 <sub>0</sub>	Word Pad (as required)		
...	Checksum			
...	Ethernet Packet Pad (as required)			

#### 8.2.4.1 Response Packet in case of Delayed Response Code

If a response includes a “Delayed Response” Code, then the response does not contain the payload of the original response. The Delayed Response shall contain a payload of a single word (uint16) including the recommended next polling time in milliseconds. If no polling time estimate is available, then the recommended next polling time shall be set to 0x0000.

**Table 13 – Generic example of Delayed Response packet payload**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..03	Response Code = 0x0004		Reason Code = 0x0000	
04..07	Reserved		Next Polling time	
08...11	Checksum			
...	Ethernet Packet Pad (as required)			

## 8.2.5 Response codes and reason codes

### 8.2.5.1 General

Response codes and reason codes are status values that are returned in the responses to NC-SI commands. The response code values provide a general categorization of the status being returned. The reason code values provide additional detail related to a particular response code.

Response codes and reason codes are divided into numeric ranges that distinguish whether the values represent standard codes that are defined in this specification or are vendor/OEM-specific values that are defined by the vendor of the controller.

The response code is a 2-byte field where values from 0x00 through 0x7F are reserved for definition by this specification. Values from 0x80 through 0xFF are vendor/OEM-specific codes that are defined by the vendor of the controller.

The reason code is a 2-byte field. The ranges of values are defined in Table 14.

**Table 14 – Reason code ranges**

MS-byte	LS-byte	Description
00h	0x00–0x7F	Standard generic reason codes  This range of values for the lower byte is used for reason codes that are not specific to a particular command but can be used as reason codes in responses for any command. The values in this range are reserved for definition by this specification.

MS-byte	LS-byte	Description
	0x80–0xFF	Vendor/OEM generic reason codes  This range of values for the lower byte is used for reason codes that are not specific to a particular command but can be used as reason codes in responses for any command. Values in this range are defined by the vendor of the controller.
Command Number  NOTE: This means that Command Number 00 cannot have any command-specific reason codes.	0x00–0x7F	Standard command-specific reason codes  This range of values for the lower byte is used for reason codes that are specific to a particular command. The upper byte holds the value of the command for which the reason code is defined. The values in this range are reserved for definition by this specification.
	0x80–0xFF	Vendor/OEM command-specific reason codes  This range of values for the lower byte is used for reason codes that are specific to a particular command. The upper byte holds the value of the command for which the reason code is defined. Values in this range are defined by the vendor of the controller.

### 8.2.5.2 Response code and reason code values

The standard response code values are defined in Table 15, and the standard reason code values are defined in Table 16. Command-specific values, if any, are defined in the clauses that describe the response data for the command. Unless otherwise specified, the standard reason codes may be used in combination with any response code. There are scenarios where multiple combinations of response and reason code values are valid. Unless otherwise specified, an implementation may return any valid combination of response and reason code values for the condition.

**Table 15 – Standard response code values**

Value	Description	Comment
0x0000	Command Completed	Returned for a successful command completion. When this response code is returned, the reason code shall be 0x0000 as described in Table 16
0x0001	Command Failed	Returned to report that a valid command could not be processed or failed to complete correctly
0x0002	Command Unavailable	Returned to report that a command is temporarily unavailable for execution because the controller is in a transient state, busy condition, or in need of external intervention.
0x0003	Command Unsupported	Returned to report that a command is not supported by the implementation. The reason code “Unknown / Unsupported Command Type” should be returned along with this response code for all unsupported commands.
0x0004	Delayed Response	Returned to report that the command was accepted, and the NC started to handle it, but it cannot respond within T5 seconds with a final answer.  When this response code is provided, the reason code shall be 0x0000.
0x8000–0xFFFF	Vendor/OEM-specific	Response codes defined by the vendor of the controller

2193

Table 16 – Standard Reason Code Values

Value	Description	Comment
0x0000	No Error/No Reason Code	When used with the Command Completed response code, indicates that the command completed normally. Otherwise this value indicates that no additional reason code information is being provided.
0x0001	Interface Initialization Required	Returned for all commands except Select/Deselect Package commands when the channel is in the Initial State, until the channel receives a Clear Initial State command
0x0002	Parameter Is Invalid, Unsupported, or Out-of-Range	Returned when a received parameter value is outside of the acceptable values for that parameter
0x0003	Channel Not Ready	Returned when the channel is in a transient state in which it is unable to process commands normally
0x0004	Package Not Ready	Returned when the package and channels within the package are in a transient state in which normal command processing cannot be done
0x0005	Invalid payload length	Returned when the payload length in the command is incorrect for the given command
0x0006	Information not available	Returned when the channel is unable to provide response data to a valid supported command.
0x0007	Intervention Required	May be returned for all commands, except for Select and Deselect Package, when the Package is not ready and requires intervention to restore its operational state. When this code is returned, the NC does not check if the command is otherwise valid and the defined response is not returned.
0x0008	Link Command Failed-Hardware Access Error	Returned when PHY R/W access fails on Link commands
0x0009	Command Timeout	Command execution has exceeded the allocated T5 time
0x000A	Secondary Device Not Powered	A device that communicates with the NC is not powered up and cannot respond to the request
0x000B-0x7FFE	Reserved	
0x7FFF	Unknown / Unsupported Command Type	Returned when the command type is unknown or unsupported. This reason code shall only be used when the response code is 0x0003 (Command Unsupported) as described in Table 15.
0x8000-0xFFFF	OEM Reason Code	Vendor-specific reason code defined by the vendor of the controller

## 2194 8.2.6 AEN packet format

2195 AEN packets shall follow the general packet format of Control Packets, with the IID field set to 0 because,  
 2196 by definition, the Management Controller does not send a response packet to acknowledge an AEN  
 2197 packet. The Control Packet Type field shall have the value 0xFF. The originating Network Controller shall  
 2198 fill in the Channel ID (Ch. ID) field with its own ID to identify itself as the source of notification. The AEN  
 2199 Type field contains the identifier of what condition caused the generation of the AEN packet.

2200 Table 17 represents the AEN packet format to be used for AENs defined in this specification.

2201

Table 17 – AEN packet format

Bits				
Bytes	31..24	23..16	15..08	07..00
00..03	MC ID = 0x0	0x01	Reserved	IID = 0x0
04..07	Control Packet Type = 0xFF	Originating Ch. ID	Reserved	Payload Length
08..11	Reserved			
12..15	Reserved			
16..19	Reserved			AEN Type

2202 Table 18 represents the AEN type ranges to be used for AENs defined in this specification.

2203

Table 18 – AEN Type Ranges

Value	AEN Type Allocation
0x0 . . 0x6F	Specification-defined AENs see clause 8.6; all others are Reserved
0x70 . . 0x7F	Transport-specific AENs
0x80 . . 0xFF	OEM-specific AENs

2204 8.2.7 Single OEM AEN packet format

2205 OEM AEN packets shall conform to the format shown in Table 19 below for NCs that only support AENs  
2206 using a single OEM identifier including NCs that implement spec version 1.1 and lower.

2207

Table 19 – OEM AEN packet format

Bits				
Bytes	31..24	23..16	15..08	07..00
00..03	MC ID = 0x0	0x01	Reserved	IID = 0x0
04..07	Control Packet Type = 0xFF	Originating Ch. ID	Reserved	Payload Length
08..11	Reserved			
12..15	Reserved			
16..19	Reserved			AEN Type
20..23	OPTIONAL AEN Data			
24..27	Checksum			

2208 8.2.8 Multiple OEMs AEN packet format

2209 OEM AEN packets shall conform to the format shown in Table 20 below for NCs that support multiple  
2210 OEM AENs and implement the Query and Set OEM AEN command.

2211

Table 20 – Multiple OEMs AEN packet format

Bits				
Bytes	31..24	23..16	15..08	07..00
00..03	MC ID = 0x0	0x01	Reserved	IID = 0x0
04..07	Control Packet Type = 0xFF	Originating Ch. ID	Reserved	Payload Length
08..11	Reserved			
12..15	Reserved			
16..19	Reserved		Multi field	AEN Type
	Manufacturer ID (IANA)			
20..23	OPTIONAL AEN Data			
24..27	Checksum			

2212 **8.2.8.1 Multi field**

2213 This field has a value of 0x01 to indicate the AEN contains a Manufacturer ID (IANA).

2214 **8.3 Control Packet type definitions**

2215 Command packet types are in the range of 0x00 to 0x7F. Table 21 describes each command, its  
 2216 corresponding response, and the type value for each. Table 21 includes commands addressed to either a  
 2217 package or a channel. The commands addressed to a package are highlighted with gray background.  
 2218 PLDM and OEM-specific commands carried over NC-SI may be package specific or channel specific or  
 2219 both.

2220 Mandatory (M), Optional (O), and Conditional (C) refer to command support requirements for the Network  
 2221 Controller.

2222 Ethernet (E), Fibre Channel (FC) and InfiniBand (IB) columns under the Fabric Implementation heading  
 2223 refer to the specific requirements of the NC implementing the network fabric type configured on the  
 2224 channel.

2225 Table 21 – Command and Response types

Control Packet Type	Command Name	Description	Response Packet Type	Fabric Implementation		
				E	FC	IB
0x00	Clear Initial State	Used by the Management Controller to acknowledge that the Network Controller is in the Initial State	0x80	M	M	M
0x01	Select Package	Used to explicitly select a controller package to transmit packets through the NC-SI interface	0x81	M	M	M

Control Packet Type	Command Name	Description	Response Packet Type	Fabric Implementation		
				E	FC	IB
0x02	Deselect Package	Used to explicitly instruct the controller package to stop transmitting packets through the NC-SI interface	0x82	M	M	M
0x03	Enable Channel	Used to enable the NC-SI channel and to cause the forwarding of bidirectional Management Controller packets to start	0x83	M	M	M
0x04	Disable Channel	Used to disable the NC-SI channel and to cause the forwarding of bidirectional Management Controller packets to cease	0x84	M	M	M
0x05	Reset Channel	Used to synchronously put the Network Controller back to the Initial State	0x85	M	M	M
0x06	Enable Channel Network TX	Used to explicitly enable the channel to transmit Pass-through packets onto the network	0x86	M	N/A	N/A
0x07	Disable Channel Network TX	Used to explicitly disable the channel from transmitting Pass-through packets onto the network	0x87	M	N/A	N/A
0x08	AEN Enable	Used to control generating AENs	0x88	C	C	C
0x09	Set Link	Used during OS absence to force link settings, or to return to auto-negotiation mode	0x89	M	N/A	N/A
0x0A	Get Link Status	Used to get current link status information	0x8A	M	N/A	N/A
0x0B	Set VLAN Filter	Used to program VLAN IDs for VLAN filtering	0x8B	M	N/A	N/A
0x0C	Enable VLAN	Used to enable VLAN filtering of Management Controller RX packets	0x8C	M	N/A	N/A
0x0D	Disable VLAN	Used to disable VLAN filtering	0x8D	M	N/A	N/A
0x0E	Set MAC Address	Used to configure and enable unicast and multicast MAC address filters	0x8E	M	N/A	N/A

Control Packet Type	Command Name	Description	Response Packet Type	Fabric Implementation		
				E	FC	IB
0x10	Enable Broadcast Filter	Used to enable selective broadcast packet filtering	0x90	M	N/A	N/A
0x11	Disable Broadcast Filter	Used to disable all broadcast packet filtering, and to enable the forwarding of all broadcast packets	0x91	M	N/A	N/A
0x12	Enable Global Multicast Filter	Used to enable selective multicast packet filtering	0x92	C	N/A	N/A
0x13	Disable Global Multicast Filter	Used to disable all multicast packet filtering, and to enable forwarding of all multicast packets	0x93	C	N/A	N/A
0x14	Set NC-SI Flow Control	Used to configure <a href="#">IEEE 802.3</a> flow control on RBT	0x94	O	N/A	N/A
0x15	Get Version ID	Used to get controller-related version information	0x95	M	M	M
0x16	Get Capabilities	Used to get optional functions supported by the NC-SI	0x96	M	M	M
0x17	Get Parameters	Used to get configuration parameter values currently in effect on the controller	0x97	M	M	M
0x18	Get Controller Packet Statistics	Used to get current packet statistics for the Ethernet Controller	0x98	O	N/A	O
0x19	Get NC-SI Statistics	Used to request the packet statistics specific to the NC-SI	0x99	O	O	O
0x1A	Get NC-SI Pass-through Statistics	Used to request NC-SI Pass-through packet statistics	0x9A	O	N/A	O
0x1B	Get Package Status	Used to get current status of the package.	0x9B	O	O	O
0x25	Get NC Capabilities and Settings	Used to request device configuration information and capabilities	0xA5			
0x26	<u>Set NC Configuration</u>	Used to configure device interfaces	0xA6			
0x27	Get PF Assignment	Used to request Function assignment information	0xA7			

Control Packet Type	Command Name	Description	Response Packet Type	Fabric Implementation		
				E	FC	IB
0x28	Set PF Assignment	Used to configure and enable Functions	0xA8			
0x29	Get Channel Configuration	Used to request Channel configuration information	0xA9			
0x2A	Set Channel Configuration	Used to configure operational characteristics of the Channel	0xAA			
0x2B	Get Partition Configuration	Used to request partition configuration information	0xAB			
0x2C	Set Partition Configuration	Used to configure partition operational characteristics	0xAC			
0x2D	Get Boot Config	Used to request boot protocol configuration information	0xAD			
0x2E	Set Boot Config	Used to configure boot protocol attributes	0xAE			
0x2F	Get Partition Statistics	Used to request network link statistics for the partition	0xAF			
0x31	Get FC Link Status	Used to request link and trunk status and speed for Fibre Channel ports	0xB1		M	
0x38	Get InfiniBand Link Status	Used to request link status for InfiniBand ports	0xB8			M
0x39	Get InfiniBand Statistics	Used to request port level statistics for InfiniBand ports	0xB9			M
0x47	Settings Commit	Used to request the commit of certain settings to NVRAM	0xC7			
0x48	Get ASIC Temperature	Used to request current NC ASIC and other external device temperatures from the NC	0xC8			
0x49	Get Ambient Temperature	Used to request the current ambient temperature from the NC adapter	0xC9			
0x4A	Get Transceiver Temperature	Used to request the current optical module temperature and thresholds	0xCA			
0x4B	Thermal Shutdown Control	Used to control and query the state of the thermal-based self-shutdown feature	0xCB	C	C	C

Control Packet Type	Command Name	Description	Response Packet Type	Fabric Implementation		
				E	FC	IB
0x4C	Transmit Data to NC	Used by the MC to transfer a block of data to the NC	0xCC	O	O	O
0x4D	Retrieve Data from NC	Used by the MC to transfer a block of data from the NC	0xCD	O	O	O
0x50	OEM Command	Used to request vendor-specific data	0xD0			
0x51	PLDM Request	Used for PLDM request over NC-SI over RBT	0xD1			
0x52	Get Package UUID	Returns a universally unique identifier (UUID) for the package	0xD2	O	O	O
0x51 – 0x60	Reserved for Transport Protocol Oriented Commands	Used to define transport protocol-oriented commands (e.g., PLDM over NC-SI/RBT)	0xD1 – 0xE0	O	O	O
0x51	Reserved					
0x52	Get Package UUID	Returns a universally unique identifier (UUID) for the package	0xD2	O	O	O
0x53	PLDM	Used for PLDM request over NC-SI over RBT	0xD3	O	O	O
0x54	Get Supported Media	See MCTP <a href="#">DSP0261</a> for full definition This command may be used on any transport	0xD4			
0x55	Transport-specific AEN Enable	See MCTP <a href="#">DSP0261</a> for full definition	0xD5			
0x56	Query Pending NC PLDM Request	Used by the MC to see if the NC has any pending PLDM requests to be retrieved	0xD6	O	O	O
0x57	Send NC PLDM Reply	Used by the MC to provide a response to a previous SPDM request by the NC	0xD7	O	O	O
0x58	Get MC MAC Address	Used by the MC to retrieve MAC addresses provisioned for its use	0xD8	O	O	O

Control Packet Type	Command Name	Description	Response Packet Type	Fabric Implementation		
				E	FC	IB
0x60	Transfer SPDM	Used by the MC to transfer a SPDM payload to or from the NC	0xE0	O	O	O
0x61	Query Pending SPDM Request	Used by the MC to see if the NC has any pending SPDM requests to be retrieved	0xE1	O	O	O
0x62	Send NC SPDM Reply	Used by the MC to respond to a previously read SPDM command from the NC	0xE2	O	O	O

## 8.4 Transport-specific Control Packet type definitions

Transport-specific control packet types are defined specifically for operation over RBT. In MCTP implementations the native message types would be used. Table 22 describes each command, its corresponding response, and the type value for each. Table 22 includes commands addressed to either a package or a channel. The commands addressed to a package are highlighted with gray background. PLDM and OEM-specific commands carried over NC-SI may be package specific or channel specific or both.

Mandatory (M), Optional (O), and Conditional (C) refer to command support requirements for the Network Controller.

Ethernet (E), Fibre Channel (FC) and InfiniBand (IB) columns under the Fabric Implementation heading refer to the specific requirements of the NC implementing the network fabric type configured on the channel.

**Table 22 – Transport-specific Command and Response types**

Control Packet Type	Command Name	Description	Response Packet Type	Fabric Implementation		
				E	FC	IB
				M	M	M

## 8.5 Command and response packet formats

This clause describes the format for each of the NC-SI commands and corresponding responses.

The corresponding response packet format shall be mandatory when a given command is supported.

### 8.5.1 NC-SI command frame format

Table 23 illustrates the NC-SI frame format that shall be accepted by the Network Controller.

2244

Table 23 – Example of complete minimum-sized NC-SI command packet

	Bits				
Bytes	31..24		23..16	15..08	07..00
00..03	0xFF		0xFF	0xFF	0xFF
04..07	0xFF		0xFF	0xFF	0xFF
08..11	0xFF		0xFF	0xFF	0xFF
12..15	0x88F8			MC ID	Header Revision
16..19	Reserved		IID	Command Type	Ch. ID

52..55	Pad
56..59	Pad
60..63	FCS

### 2248 8.5.3 Clear Initial State command (0x00)

2249 The Clear Initial State command provides the mechanism for the Management Controller to acknowledge  
 2250 that it considers a channel to be in the Initial State (typically because the Management Controller received  
 2251 an “Interface Initialization Required” reason code) and to direct the Network Controller to start accepting  
 2252 commands for initializing or recovering the NC-SI operation. When in the Initial State, the Network  
 2253 Controller shall return the “Interface Initialization Required” reason code for all channel commands until it  
 2254 receives the Clear Initial State command.

2255 If the channel is in the Initial State when it receives the Clear Initial State command, the command shall  
 2256 cause the Network Controller to stop returning the “Interface Initialization Required” reason code. The  
 2257 channel shall also treat any subsequently received instance ID numbers as IDs for new command  
 2258 instances, not retries.

2259 If the channel is not in the Initial State when it receives this command, it shall treat any subsequently  
 2260 received instance ID numbers as IDs for new command instances, not retries.

2261 Table 25 illustrates the packet format of the Clear Initial State command.

2262 **Table 25 – Clear Initial State command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

### 2263 8.5.4 Clear Initial State response (0x80)

2264 Currently no command-specific reason code is identified for this response (see Table 26).

2265 **Table 26 – Clear Initial State response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

### 2266 8.5.5 Select Package command (0x01)

2267 A package is considered to be “selected” when its NC-SI output buffers are allowed to transmit packets  
2268 through the NC-SI interface. Conversely, a package is “deselected” when it is not allowed to transmit  
2269 packets through the NC-SI interface.

2270 The Select Package command provides a way for a Management Controller to explicitly take a package  
2271 out of the deselected state and to control whether hardware arbitration is enabled for the package.  
2272 (Similarly, the Deselect Package command allows a Management Controller to explicitly deselect a  
2273 package.)

2274 The NC-SI package in the Network Controller shall also become selected if the package receives any NC-  
2275 SI command (other than Deselect Package) that is directed to the package or to a channel within the  
2276 package.

2277 The Select Package command is addressed to the package, rather than to a channel (that is, the  
2278 command is sent with a Channel ID where the Package ID subfield matches the ID of the intended  
2279 package and the Internal Channel ID subfield is set to 0x1F).

2280 More than one package can be in the selected state simultaneously if hardware arbitration is used  
2281 between the selected packages and is active. The hardware arbitration logic ensures that buffer conflicts  
2282 will not occur between selected packages.

2283 If hardware arbitration is not active or is not used for a given package, only one package shall be selected  
2284 at a time. To switch between packages, the Deselect Package command is used by the Management  
2285 Controller to put the presently selected package into the deselected state before another package is  
2286 selected.

2287 A package shall stay in the selected state until it receives a Deselect Package command unless an  
2288 internal condition causes all internal channels to enter the Initial State.

2289 A package that is not using hardware arbitration may leave its output buffers enabled for the time that it is  
2290 selected, or it may place its output buffers into the high-impedance state between transmitting packets  
2291 through the NC-SI interface. (Temporarily placing the output buffers into the high-impedance state is not  
2292 the same as entering the deselected state.)

2293 For Type A integrated controllers: Because the RBT bus buffers are separately controlled, a separate  
2294 Select Package command needs to be sent to each Package ID in the controller that is to be enabled to  
2295 transmit through the NC-SI interface. If the internal packages do not support hardware arbitration, only  
2296 one package shall be selected at a time; otherwise, a bus conflict will occur.

2297 For Type S single channel, and Types B and C integrated controllers: A single set of RBT bus buffers  
2298 exists for the package. Sending a Select Package command selects the entire package and enables all  
2299 channels within the package to transmit through the NC-SI interface. (Whether a particular channel in a  
2300 selected package starts transmitting Pass-through and AEN packets depends on whether that channel  
2301 was enabled or disabled using the Enable or Disable Channel commands and whether the package may  
2302 have had packets queued up for transmission.)

2303 Implementation Note: The features control settings are only configurable via this command and are not  
2304 altered by ‘implicit’ selection as described in clause 6.1.14.4.

2305 Table 27 illustrates the packet format of the Select Package command.

2306 Table 28 illustrates the disable byte for hardware arbitration.

2307

**Table 27 – Select Package command packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Reserved			Features Control

24..45	Pad			

2308

2309

**Table 28 – Features Control byte**

Bits	Description
0	<p>0b = Hardware arbitration between packages is enabled.</p> <p>1b = Disable hardware arbitration. Disabling hardware arbitration causes the package's arbitration logic to enter or remain in bypass mode.</p> <p>In the case that the Network Controller does not support hardware arbitration, this bit is ignored; the Network Controller shall not return an error if the Select Package command can otherwise be successfully processed.</p>
1	<p>Delayed Response Enable:</p> <p>0b = NC is not allowed to use the "Delayed Response" response code (default)</p> <p>1b = NC is allowed to use the "Delayed Response" response code</p>
7..2	Reserved

**2310 8.5.6 Select Package response (0x81)**

2311 Currently no command-specific reason code is identified for this response (see Table 29).

2312

**Table 29 – Select package response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

**2313 8.5.7 Deselect Package command (0x02)**2314 The Deselect Package command directs the controller package to stop transmitting packets through the  
2315 NC-SI interface and to place the output buffers for the package into the high-impedance state.2316 The Deselect Package command is addressed to the package, rather than to a particular channel (that is,  
2317 the command is sent with a Channel ID where the Package ID subfield matches the ID of the intended  
2318 package and the Internal Channel ID subfield is set to 0x1F).

2319 The controller package enters the deselected state after it has transmitted the response to the Deselect  
 2320 Package command and placed its buffers into the high-impedance state. The controller shall place its  
 2321 outputs into the high-impedance state within the Package Deselect to Hi-Z Interval (T1). (This interval  
 2322 gives the controller being deselected time to turn off its electrical output buffers after sending the  
 2323 response to the Deselect Package command.)

2324 If hardware arbitration is not supported or used, the Management Controller should wait for the Package  
 2325 Deselect to Hi-Z Interval (T1) to expire before selecting another controller.

2326 For Type A integrated controllers: Because the bus buffers are separately controlled, putting the overall  
 2327 controller package into the high-impedance state requires sending separate Deselect Package  
 2328 commands to each Package ID in the overall package.

2329 For Type S single channel, and Types B and C integrated controllers: A single set of bus buffers exists for  
 2330 the package. Sending a Deselect Package command deselects the entire NC-SI package and prevents  
 2331 all channels within the package from transmitting through the NC-SI interface.

2332 Table 30 illustrates the packet format of the Deselect Package command.

2333 **Table 30 – Deselect Package command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

## 2334 8.5.8 Deselect Package response (0x82)

2335 The Network Controller shall always put the package into the deselected state after sending a Deselect  
 2336 Package Response.

2337 No command-specific reason code is identified for this response (see Table 31).

2338 **Table 31 – Deselect Package response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

**8.5.9 Enable Channel command (0x03)**

The Enable Channel command shall enable the Network Controller to allow transmission of Pass-through and AEN packets to the Management Controller through the NC-SI.

Table 32 illustrates the packet format of the Enable Channel command.

**Table 32 – Enable Channel command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

**8.5.10 Enable Channel response (0x83)**

No command-specific reason code is identified for this response (see Table 33).

**Table 33 – Enable Channel response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

**8.5.11 Disable Channel command (0x04)**

The Disable Channel command allows the Management Controller to disable the flow of packets, including Pass-through and AEN, to the Management Controller.

A Network Controller implementation is not required to flush pending packets from its RX Queues when a channel becomes disabled. If queuing is subsequently disabled for a channel, it is possible that a number of packets from the disabled channel could still be pending in the RX Queues. These packets may continue to be transmitted through the NC-SI interface until the RX Queues are emptied of those packets. The Management Controller should be aware that it may receive a number of packets from the channel before receiving the response to the Disable Channel command.

The 1-bit Allow Link Down (ALD) field can be used by the Management Controller to indicate that the link corresponding to the specified channel is not required after the channel is disabled. The Network Controller is allowed to take down the external network physical link if no other functionality (for example, host OS or WoL [Wake-on-LAN]) is active.

Possible values for the 1-bit ALD field are as follows:

- 0b = Keep link up (establish and/or keep a link established) while channel is disabled
- 1b = Allow link to be taken down while channel is disabled

Table 34 illustrates the packet format of the Disable Channel command.

2364

**Table 34 – Disable Channel command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Reserved			ALD
20..23	Checksum			
24..45	Pad			

2365 NOTE: It is currently unspecified whether this command will cause the Network Controller to cease the passing  
 2366 through of traffic from the Management Controller to the network, or if this can only be done using the Disable  
 2367 Channel Network TX command.

### 2368 8.5.12 Disable Channel response (0x84)

2369 No command-specific reason code is identified for this response (see Table 35).

2370

**Table 35 – Disable Channel response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00

16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

### 2371 8.5.13 Reset Channel command (0x05)

2372 The Reset Channel command allows the Management Controller to put the channel into the Initial State.  
 2373 Packet transmission is not required to stop until the Reset Channel response has been sent. Thus, the  
 2374 Management Controller should be aware that it may receive a number of packets from the channel before  
 2375 receiving the response to the Reset Channel command.

2376 Table 36 illustrates the packet format of the Reset Channel command.

2377

**Table 36 – Reset Channel command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00

24..45	Pad			

**2381 8.5.15 Enable Channel Network TX command (0x06)**

2382 The Enable Channel Network TX command shall enable the channel to transmit Pass-through packets  
 2383 onto the network. After network transmission is enabled, this setting shall remain enabled until a Disable  
 2384 Channel Network TX command is received, or the channel enters the Initial State.

2385 The intention of this command is to control which Network Controller ports are allowed to transmit to the  
 2386 external network. The Network Controller compares the source MAC address in outgoing Pass-through  
 2387 packets to the unicast MAC address(es) configured using the Set MAC Address command. If a match  
 2388 exists, the packet is transmitted to the network.

2389 Table 38 illustrates the packet format of the Enable Channel Network TX command.

2390

**Table 38 – Enable Channel Network TX command packet format**

Bits

24..45	Pad			

**2394 8.5.17 Disable Channel Network TX command (0x07)**

2395 The Disable Channel Network TX command disables the channel from transmitting Pass-through packets  
 2396 onto the network. After network transmission is disabled, it shall remain disabled until an Enable Channel  
 2397 Network TX command is received.

2398 Table 40 illustrates the packet format of the Disable Channel Network TX command.

2399 **Table 40 – Disable Channel Network TX command packet format**

20..23	Pad			

#### 2400 8.5.18 Disable Channel Network TX response (0x87)

2401 The NC-SI shall, in the absence of a checksum error or identifier mismatch, always accept the Disable  
2402 Channel Network TX command and send a response.

2403 Currently no command-specific reason code is identified for this response (see Table 41).

2404 **Table 41 – Disable Channel Network TX response packet format**

24..45	Pad			

#### 2405 8.5.19 AEN Enable command (0x08)

2406 Network Controller implementations shall support this command on the condition that the Network  
2407 Controller generates one or more standard AENs. The AEN Enable command enables and disables the  
2408 different standard AENs supported by the Network Controller. The Network Controller shall copy the AEN  
2409 MC ID field from the AEN Enable command into the MC ID field in every subsequent AEN sent to the  
2410 Management Controller.

2411 For more information, see clauses 8.6 ("AEN packet formats") and 8.2.1.1 ("Management Controller ID").

2412 Control of transport-specific AENs is outside the scope of this specification and should be defined by the  
2413 transport binding specifications.

2414 Table 42 illustrates the packet format of the AEN Enable command.

2415 **Table 42 – AEN Enable command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00

2416 The AEN Control field has the format shown in Table 43.

2417 **Table 43 – Format of AEN control**

Bit Position	Field Description	Value Description
0	Link Status Change AEN control	0b = Disable Link Status Change AEN 1b = Enable Link Status Change AEN
1	Configuration Required AEN control	0b = Disable Configuration Required AEN 1b = Enable Configuration Required AEN
2	Host NC Driver Status Change AEN control	0b = Disable Host NC Driver Status Change AEN 1b = Enable Host NC Driver Status Change AEN
3	Delayed Response Ready AEN control	0b = Disable Delayed Response Ready AEN 1b = Enable Delayed Response Ready AEN
4	InfiniBand Link Status Change AEN control	0b = Disable IB Link Status Change AEN 1b = Enable IB Link Status Change AEN
5	Fibre Channel Link Status Change AEN control	0b = Disable FC Link Status Change AEN 1b = Enable FC Link Status Change AEN
6	Transceiver Event AEN Control	0b = Disable Transceiver Event AEN 1b = Enable Transceiver Event AEN
7	Request Data Transfer AEN control	0b = Disable Request Data Transfer AEN 1b = Enable Request Data Transfer AEN
8	Partition Link Status Change AEN control	0b = Disable Partition Link Status Change AEN 1b = Enable Partition Link Status Change AEN
9	Thermal Shutdown Event AEN control	0b = Disable Thermal Shutdown Event AEN 1b = Enable Thermal Shutdown Event AEN
15..10	Reserved	Reserved
31..16	OEM-specific AEN control	OEM-specific control

## 2418 8.5.20 AEN Enable response (0x88)

2419 Currently no command-specific reason code is identified for this response (see Table 44). If the MC  
2420 attempts to set an AEN type that is not supported, the NC shall reject the entire command even if it also

2421 includes valid AENs and respond with the “Command Failed” response and “Parameter Is Invalid...”  
 2422 reason codes.

2423 **Table 44 – AEN Enable response packet format**

20..23	Checksum			
24..45	Pad			

### 2424 8.5.21 Set Link command (0x09)

2425 The Set Link command may be used by the Management Controller to configure the external network  
 2426 interface associated with the channel by using the provided settings. Upon receiving this command, while  
 2427 the host NC driver is not operational, the channel shall attempt to set the link to the configuration  
 2428 specified by the parameters. Upon successful completion of this command, link settings specified in the  
 2429 command should be used by the network controller as long as the host NC driver does not overwrite the  
 2430 link settings.

2431 In the absence of an operational host NC driver, the NC should attempt to make the requested link state  
 2432 change even if it requires the NC to drop the current link. The channel shall send a response packet to  
 2433 the Management Controller within the required response time. However, this specification does not  
 2434 specify the amount of time the requested link state changes may take to complete.

2435 The actual link settings are controlled by the host NC driver when it is operational. When the host NC  
 2436 driver is operational, link settings specified by the MC using the Set Link command may be overwritten by  
 2437 the host NC driver. The link settings are not restored by the NC if the host NC driver becomes non-  
 2438 operational.

2439 Table 45 illustrates the packet format of the Set Link command.

2440 **Table 45 – Set Link command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Link Settings			
20..23	OEM Link Settings			
24..27	Checksum			
28..45	Pad			

2441 Table 46 and Table 47 describe the Set Link bit definitions. Refer to [IEEE 802.3](#) for definitions of Auto  
 2442 Negotiation, Duplex Setting, Pause Capability, and Asymmetric Pause Capability.

2443

Table 46 – Set Link bit definitions

Bit Position	Field Description	Value Description
00	Auto Negotiation If Auto Negotiation is not used, only one combination of single link speed, protocol and FEC settings is allowed to be configured, otherwise a Command Failed response code and Parameter Is Invalid, Unsupported, or Out-of-Range reason code shall be returned.	1b = enable 0b = disable
01..07	Link Speed Selection More than one speed can be selected when Auto Negotiation is set to 'enable'. If Auto Negotiation is not used, the channel attempts to force the link to the specified setting (in this case, if the setting is not supported or if multiple speeds are enabled, a Command Failed response code and Parameter Is Invalid, Unsupported, or Out-of-Range reason code shall be returned). . If multiple settings are enabled, a Command Failed response code and Set Link Speed Conflict reason code shall be returned) NOTE Additional link speeds are defined below.	Bit 01: 1b = enable 10 Mbps
		Bit 02: 1b = enable 100 Mbps
		Bit 03: 1b = enable 1000 Mbps (1 Gbps)
		Bit 04: 1b = enable 10 Gbps
		Bit 05: 1b = enable 20 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0)
		Bit 06: 1b = enable 25 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0)
		Bit 07: 1b = enable 40 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0)
08..09	Duplex Setting (separate duplex setting bits) More than one duplex setting can be selected when Auto Negotiation is set to 'enable'. If Auto Negotiation is not used, the channel attempts to force the link to the specified setting (in this case, if the setting is not supported or if multiple settings are enabled, a Command Failed response code and Parameter Is Invalid, Unsupported, or Out-of-Range reason code shall be returned."	Bit 08: 1b = enable half-duplex
		Bit 09: 1b = enable full-duplex
10	Pause Capability If Auto Negotiation is not used, the channel should apply pause settings assuming the partner supports the same capability.	1b = disable 0b = enable
11	Asymmetric Pause Capability If Auto Negotiation is not used, the channel should apply asymmetric pause settings assuming the partner supports the same capability.	1b = enable 0b = disable
12	OEM Link Settings Field Valid (see Table 47)	1b = enable 0b = disable
13..19	Additional Link Speeds (see Link Speed Selection)	Bit 13: 1b = enable 50 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0) Bit 14: 1b = enable 100 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0) Bit 15: 1b = enable 2.5 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0)

Bit Position	Field Description	Value Description
		Bit 16: 1b = enable 5 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0)  Bit 17: 1b = enable 200 Gbps (optional for NC-SI 1.2, Reserved for NC-SI 1.1/1.0)  Bit 18: 1b = enable 400 Gbps (optional for NC-SI 1.2, Reserved for NC-SI 1.1/1.0)  Bit 19: 1b = enable 800 Gbps (optional for NC-SI 1.2, Reserved for NC-SI 1.1/1.0)
20..21	Reserved	
22..23	Modulation Scheme	Bit 22: 1b = NRZ (optional for NC-SI 1.2, Reserved for NC-SI 1.1/1.0)  Bit 23: 1b = PAM-4 (optional for NC-SI 1.2, Reserved for NC-SI 1.1/1.0)  Bit 23-22 Values: 00 – Use default 01 – Enable NRZ 10 – Enable PAM-4 11 – Enable NRZ and PAM-4
24..27	Forward Error Correction (FEC) Algorithm	Bit 24: 1b = BASE-R FEC (Firecode) (optional for NC-SI 1.2, Reserved for NC-SI 1.1/1.0)  Bit 25: 1b = RS-FEC (Reed Solomon) (optional for NC-SI 1.2, Reserved for NC-SI 1.1/1.0)  Bit 26..27 Reserved  If all bits are set to 0, then no FEC algorithm shall be selected
28	Energy Efficient Ethernet (EEE)	1b = enable 0b = disable
29	Link Training (LT)	1b = enable 0b = disable
30	Parallel Detect An auto-negotiation link partner's mechanism to establish links with non-negotiation, fixed-speed linked partners.	1b = enable 0b = disable
31	Reserved	0

2444

Table 47 – OEM Set Link bit definitions

Bit Position	Field Description	Value Description
00..31	OEM Link Settings	Vendor specified

## 8.5.22 Set Link Response (0x89)

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Set Link command and send a response (see Table 48). In the presence of an operational Host NC driver, the NC should not attempt to make link state changes and should send a response with reason code 0x1 (Set Link Host OS/ Driver Conflict).

If the Auto Negotiation field is set, the NC should ignore Link Speed Selection and Duplex Setting fields that are not supported by the NC.

**Table 48 – Set Link response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

Table 49 describes the reason codes that are specific to the Set Link command. Returning the following command-specific codes is recommended, conditional upon Network Controller support for the related capabilities.

**Table 49 – Set Link command-specific reason codes**

Value	Description	Comment
0x0901	Set Link Host OS/ Driver Conflict	Returned when the Set Link command is received when the Host NC driver is operational
0x0902	Set Link Media Conflict	Returned when Set Link command parameters conflict with the media type (for example, Fiber Media)
0x0903	Set Link Parameter Conflict	Returned when Set Link parameters conflict with each other (for example, 1000 Mbps HD with copper media)
0x0904	Set Link Power Mode Conflict	Returned when Set Link parameters conflict with current low-power levels by exceeding capability
0x0905	Set Link Speed Conflict	Returned when Set Link parameters attempt to force more than one speed at the same time when Auto Negotiation is disabled
0x0906	Link Command Failed-Hardware Access Error	Returned when PHY R/W access fails to complete normally while executing the Set Link or Get Link Status command
0x0907	Set Link SerDes Conflict	Returned when Set Link parameters attempt to force an unsupported SerDes configuration
0x0908	Set Link FEC Conflict	Returned when Set Link parameters attempt to force an unsupported FEC algorithm
0x0909	Set Link EEE Conflict	Returned when Set Link parameters attempt to force an unsupported EEE configuration

Value	Description	Comment
0x090A	Set Link LT Conflict	Returned when Set Link parameters attempt to force an unsupported link training configuration
0x090B	Set Link Parallel Detection Conflict	Returned when Set Link parameters attempt to force an unsupported parallel detection configuration

### 2457 8.5.23 Get Link Status command (0x0A)

2458 The Get Link Status command allows the Management Controller to query the channel for potential link  
 2459 status and error conditions (see Table 50).

2460 **Table 50 – Get Link Status command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum

00..31	OEM Link Status	OEM specific

2472 Table 55 describes the reason code that is specific to the Get Link Status command.

2473 **Table 55 – Get Link Status command-specific reason code**

Value	Description	Comment
0x0A06	Link Command Failed-Hardware Access Error	Returned when PHY R/W access fails to complete normally while executing the Set Link or Get Link Status command

## 2474 8.5.25 Set VLAN Filter command (0x0B)

2475 The Set VLAN Filter command is used by the Management Controller to program one or more VLAN IDs  
2476 that are used for VLAN filtering.

2477 Incoming packets that match both a VLAN ID filter and a MAC address filter are forwarded to the  
2478 Management Controller. Other packets may be dropped based on the VLAN filtering mode per the Enable  
2479 VLAN command.

2480 The quantity of each filter type that is supported by the channel can be discovered by means of the Get  
2481 Capabilities command. Up to 15 filters can be supported per channel. A Network Controller  
2482 implementation shall support at least one VLAN filter per channel.

2483 To configure a VLAN filter, the Management Controller issues a Set VLAN Filter command with the Filter  
2484 Selector field indicating which filter is to be configured, the VLAN ID field set to the VLAN TAG values to  
2485 be used by the filter, and the Enable field set to either enable or disable the selected filter.

2486 The VLAN-related fields are specified per [IEEE 802.1q](#). When VLAN Tagging is used, the packet includes  
2487 a Tag Protocol Identifier (TPID) field and VLAN Tag fields, as shown in Table 56.

2488

**Table 56 – IEEE 802.1q VLAN Fields**

Field	Size	Description
TPI	2 bytes	Tag Protocol Identifier = 8100h
VLAN TAG – user priority	3 bits	User Priority (typical value = 000b)
VLAN TAG – CFI	1 bit	Canonical Format Indicator = 0b
VLAN TAG – VLAN ID	12 bits	Zeros = no VLAN

2489 When checking VLAN field values, the Network Controller shall match against the enabled VLAN Tag  
 2490 Filter values that were configured with the S0065t VLAN Filter command. The Network Controller shall  
 2491 also match on the TPI value of 8100h, as specified by [IEEE 802.1q](#). Matching against the User  
 2492 Priority/CFI bits is optional. An implementation may elect to ignore the setting of those fields.

2493 Table 57 illustrates the packet format of the Set VLAN Filter command.

2494

**Table 57 – Set VLAN Filter command packet format**

	Bits				
Bytes	31..24	23..16	15..08	07..00

Value	Description
0b	Disable this VLAN filter
1b	Enable this VLAN filter

**8.5.26 Set VLAN Filter response (0x8B)**

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Set VLAN Filter command and send a response (see Table 60).

**Table 60 – Set VLAN Filter response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

Table 61 describes the reason code that is specific to the Set VLAN Filter command.

**Table 61 – Set VLAN Filter command-specific reason code**

Value	Description	Comment
0x0B07	VLAN Tag Is Invalid	Returned when the VLAN ID is invalid (VLAN ID = 0)

**8.5.27 Enable VLAN command (0x0C)**

The Enable VLAN command may be used by the Management Controller to enable the channel to accept VLAN-tagged packets from the network for NC-SI Pass-through operation (see Table 62).

**Table 62 – Enable VLAN command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Reserved			Mode #
20..23	Checksum			
24..45	Pad			

Table 63 describes the modes for the Enable VLAN command.

**Table 63 – VLAN Enable modes**

Mode	#	O/M	Description
Reserved	0x00	N/A	Reserved
VLAN only	0x01	M	Only VLAN-tagged packets that match the enabled VLAN Filter settings (and also match the MAC Address Filtering configuration) are accepted. Non-VLAN-tagged packets are not accepted.

VLAN + non-VLAN	0x02	O	VLAN-tagged packets that match the enabled VLAN Filter settings (and also match the MAC Address Filtering configuration) are accepted.  Non-VLAN-tagged packets (that also match the MAC Address Filtering configuration) are also accepted.
Any VLAN + non-VLAN	0x03	O	Any VLAN-tagged packets that also match the MAC Address Filtering configuration are accepted, regardless of the VLAN Filter settings.  Non-VLAN-tagged packets (that also match the MAC Address Filtering configuration) are also accepted.
Reserved	0x04 – 0xFF	N/A	Reserved

### 8.5.28 Enable VLAN response (0x8C)

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Enable VLAN command and send a response.

Currently no command-specific reason code is identified for this response (see Table 64).

**Table 64 – Enable VLAN response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

### 8.5.29 Disable VLAN command (0x0D)

The Disable VLAN command may be used by the Management Controller to disable VLAN filtering. In the disabled state, only non-VLAN-tagged packets (that also match the MAC Address Filtering configuration) are accepted. VLAN-tagged packets are not accepted.

Table 65 illustrates the packet format of the Disable VLAN command.

**Table 65 – Disable VLAN command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

### 8.5.30 Disable VLAN response (0x8D)

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Disable VLAN command and send a response.

Currently no command-specific reason code is identified for this response (see Table 66).

**Table 66 – Disable VLAN response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header

20..23	Checksum			
24..45	Pad			

### 8.5.31 Set MAC Address command (0x0E)

The Set MAC Address command is used by the Management Controller to program the channel's unicast or multicast MAC address filters.

The channel supports one or more “perfect match” MAC address filters that are used to selectively forward inbound frames to the Management Controller. Assuming that a packet passes any VLAN filtering that may be active, it will be forwarded to the Management Controller if its 48-bit destination MAC address exactly matches an active MAC address filter.

MAC address filters may be configured as unicast or multicast addresses, depending on the capability of the channel. The channel may implement three distinct types of filter:

- **Unicast filters** support exact matching on 48-bit unicast MAC addresses (AT = 0x0 only).
- **Multicast filters** support exact matching on 48-bit multicast MAC addresses (AT = 0x1 only).
- **Mixed filters** support matching on both unicast and multicast MAC addresses. (AT = 0x0 or AT = 0x1)

The number of each type of filter that is supported by the channel can be discovered by means of the Get Capabilities command. The channel shall support at least one unicast address filter or one mixed filter, so that at least one unicast MAC address filter may be configured on the channel. Support for any combination of unicast, multicast, or mixed filters beyond this basic requirement is vendor specific. The total number of all filters shall be less than or equal to 8.

To configure an address filter, the Management Controller issues a Set MAC Address command with the Address Type field indicating the type of address to be programmed (unicast or multicast) and the MAC Address Num field indicating the specific filter to be programmed.

Filters are addressed using a 1-based index ordered over the unicast, multicast, and mixed filters reported by means of the Get Capabilities command. For example, if the interface reports four unicast filters, two multicast filters, and two mixed filters, then MAC Address numbers 1 through 4 refer to the interface's unicast filters, 5 and 6 refer to the multicast filters, and 7 and 8 refer to the mixed filters. Similarly, if the interface reports two unicast filters, no multicast filters, and six mixed filters, then MAC address numbers 1 and 2 refer to the unicast filters, and 3 through 8 refer to the mixed filters.

2554 The filter type of the filter to be programmed (unicast, multicast, or mixed) shall be compatible with the  
 2555 Address Type being programmed. For example, programming a mixed filter to a unicast address is  
 2556 allowed, but programming a multicast filter to a unicast address is an error.

2557 The Enable field determines whether the indicated filter is to be enabled or disabled. When a filter is  
 2558 programmed to be enabled, the filter is loaded with the 48-bit MAC address in the MAC Address field of  
 2559 the command, and the channel enables forwarding of frames that match the configured address. If the  
 2560 specified filter was already enabled, it is updated with the new address provided.

2561 When a filter is programmed to be disabled, the contents of the MAC Address field are ignored. Any  
 2562 previous MAC address programmed in the filter is discarded and the channel no longer uses this filter in  
 2563 its packet-forwarding function.

2564 Only unicast MAC addresses, specified with AT set to 0x0, should be used in source MAC address  
 2565 checking and for determining the NC-SI channel for Pass-through transmit traffic.

2566 Table 67 illustrates the packet format of the Set MAC Address command.

2567 **Table 67 – Set MAC Address command packet format**

	Bits					
Bytes	31..24	23..16	15..08	07..00		
00..15	NC-SI Control Packet Header

20..23	Checksum			
24..45	Pad			

2577 Table 72 describes the reason code that is specific to the Set MAC Address command.

2578 **Table 72 – Set MAC Address command-specific reason code**

Value	Description	Comment
0x0E08	MAC Address Is Zero	Returned when the Set MAC Address command is received with the MAC address set to 0

2579 **8.5.33 Enable Broadcast Filter command (0x10)**

2580 The Enable Broadcast Filter command allows the Management Controller to control the forwarding of  
 2581 broadcast frames to the Management Controller. The channel, upon receiving and processing this  
 2582 command, shall filter all received broadcast frames based on the broadcast packet filtering settings  
 2583 specified in the payload. If no broadcast packet types are specified for forwarding, all broadcast packets  
 2584 shall be filtered out.

2585 The Broadcast Packet Filter Settings field is used to specify those protocol-specific broadcast filters that  
 2586 should be activated. The channel indicates which broadcast filters it supports in the Broadcast Filter  
 2587 Capabilities field of the Get Capabilities Response frame defined in clause 8.5.46.

2588 Table 73 illustrates the packet format of the Enable Broadcast Filter command.

2589

**Table 73 – Enable Broadcast Filter command packet format**

2591

**Table 74 – Broadcast Packet Filter Settings field**

Bit Position	Field Description	Value Description
0	ARP Packets	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an ARP broadcast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF).</li> <li>The Ethertype field set to 0x0806.</li> </ul> <p>This field is mandatory.</p>
1	DHCP Client Packets	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, a DHCP client broadcast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF).</li> <li>The Ethertype field is set to 0x0800 (IPv4).</li> <li>The IP header's Protocol field is set to 17 (UDP).</li> <li>The UDP destination port number is set to 68.</li> </ul> <p>This field is optional. If unsupported, broadcast DHCP client packets will be blocked when broadcast filtering is enabled. The value shall be set to 0 if unsupported.</p>

Bit Position	Field Description	Value Description
2	DHCP Server Packets	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, a DHCP server broadcast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF).</li> <li>The Ethertype field is set to 0x0800 (IPv4).</li> <li>The IP header's Protocol field is set to 17 (UDP).</li> <li>The UDP destination port number is set to 67.</li> </ul> <p>This field is optional. If unsupported, broadcast DHCP packets will be blocked when broadcast filtering is enabled. The value shall be set to 0b if unsupported.</p>
3	NetBIOS Packets	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, NetBIOS broadcast packets are defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF).</li> <li>The Ethertype field is set to 0x0800 (IPv4).</li> <li>The IP header's Protocol field is set to 17 (UDP).</li> <li>The UDP destination port number is set to 137 for NetBIOS Name Service or 138 for NetBIOS Datagram Service, per the assignment of IANA well-known ports.</li> </ul> <p>This field is optional. If unsupported, broadcast NetBIOS packets will be blocked when broadcast filtering is enabled. The value shall be set to 0b if unsupported.</p>
4..31	Reserved	None

#### 2592 8.5.34 Enable Broadcast Filter response (0x90)

2593 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Enable  
2594 Broadcast Filter command and send a response.

2595 Currently no command-specific reason code is identified for this response (see Table 75).

2596 **Table 75 – Enable Broadcast Filter response packet format**

Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

### 8.5.35 Disable Broadcast Filter command (0x11)

The Disable Broadcast Filter command may be used by the Management Controller to disable the broadcast filter feature and enable the reception of all broadcast frames. Upon processing this command, the channel shall discontinue the filtering of received broadcast frames.

Table 76 illustrates the packet format of the Disable Broadcast Filter command.

**Table 76 – Disable Broadcast Filter command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

### 8.5.36 Disable Broadcast Filter response (0x91)

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Disable Broadcast Filter command and send a response.

Currently no command-specific reason code is identified for this response (see Table 77).

**Table 77 – Disable Broadcast Filter response packet format**

Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

### 8.5.37 Enable Global Multicast Filter command (0x12)

The Enable Global Multicast Filter command is used to activate global filtering of multicast frames with optional filtering of specific multicast protocols. Upon receiving and processing this command, the channel shall only deliver multicast frames that match specific multicast MAC addresses enabled for Pass-through using this command or the Set MAC Address command.

The Multicast Packet Filter Settings field is used to specify optional, protocol-specific multicast filters that should be activated. The channel indicates which optional multicast filters it supports in the Multicast Filter Capabilities field of the Get Capabilities Response frame defined in clause 8.5.46. The Management Controller should not set bits in the Multicast Packet Filter Settings field that are not indicated as supported in the Multicast Filter Capabilities field.

Neighbor Solicitation messages are sent to a Solicited Node multicast address that is derived from the target node's IPv6 address. This command may be used to enable forwarding of solicited node multicasts.

The IPv6 neighbor solicitation filter, as defined in this command, may not be supported by the Network Controller. In this case, the Management Controller may configure a multicast or mixed MAC address

filter for the specific Solicited Node multicast address using the Set MAC Address command to enable forwarding of Solicited Node multicasts.

This command shall be implemented if the channel implementation supports accepting all multicast addresses. An implementation that does not support accepting all multicast addresses shall not implement these commands. Pass-through packets with multicast addresses can still be accepted depending on multicast address filter support provided by the Set MAC Address command. Multicast filter entries that are set to be enabled in the Set MAC Address command are accepted; all others are rejected. Table 78 illustrates the packet format of the Enable Global Multicast Filter command. Unsupported fields should be treated as reserved fields unless otherwise specified.

**Table 78 – Enable Global Multicast Filter command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Multicast Packet Filter Settings			
20..23	Checksum			
24..45	Pad			

Table 79 describes the bit definitions for the Multicast Packet Filter Settings field.

**Table 79 – Bit Definitions for Multicast Packet Filter Settings field**

Bit Position	Field Description	Value Description
0	IPv6 Neighbor Advertisement	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an IPv6 Neighbor Advertisement multicast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This address corresponds to the all-nodes multicast address (FF02::1).</li> <li>The Ethertype field is set to 0x86DD (IPv6).</li> <li>The IPv6 header's Next Header field is set to 58 (ICMPv6).</li> <li>The ICMPv6 header's Message Type field is set to the following value: 136 – Neighbor Advertisement.</li> </ul> <p>This field is optional.</p>

Bit Position	Field Description	Value Description
1	IPv6 Router Advertisement	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an IPv6 Router Advertisement multicast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>• The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This corresponds to the all-nodes multicast address (FF02::1).</li> <li>• The Ethertype field is set to 0x86DD (IPv6).</li> <li>• The IPv6 header's Next Header field is set to 58 (ICMPv6).</li> <li>• The ICMPv6 header's Message Type field is set to 134.</li> </ul> <p>This field is optional.</p>
2	DHCPv6 relay and server multicast	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, a DHCPv6 multicast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>• The destination MAC address field is set to the layer 2 multicast address 33:33:00:01:00:02 or 33:33:00:01:00:03. These correspond to the IPv6 multicast addresses FF02::1:2 (All_DHCP_Relay_Agents_and_Servers) and FF05::1:3 (All_DHCP_Servers).</li> <li>• The Ethertype field is set to 0x86DD (IPv6).</li> <li>• The IPv6 header's Next Header field is set to 17 (UDP).</li> <li>• The UDP destination port number is set to 547.</li> </ul> <p>This field is optional.</p>
3	DHCPv6 multicasts from server to clients listening on well-known UDP ports	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this filter, a DHCPv6 multicast packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>• The destination MAC address field is set to the layer 2 multicast address 33:33:00:01:00:02. These correspond to the IPv6 multicast addresses FF02::1:2 (All_DHCP_Relay_Agents_and_Servers).</li> <li>• The Ethertype field is set to 0x86DD (IPv6).</li> <li>• The IPv6 header's Next Header field is set to 17 (UDP).</li> <li>• The UDP destination port number is set to 546.</li> </ul> <p>This field is optional.</p>

Bit Position	Field Description	Value Description
4	IPv6 MLD	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an IPv6 MLD packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This address corresponds to the All_Nodes (FF02::1) multicast address.</li> <li>The Ethertype field is set to 0x86DD (IPv6).</li> <li>The IPv6 header's Next Header field is set to 58 (ICMPv6).</li> <li>The ICMPv6 header's Message Type field is set to one of the following values: 130 (Multicast Listener Query), 131 (Multicast Listener Report), 132 (Multicast Listener Done)</li> </ul> <p>This field is optional.</p>
5	IPv6 Neighbor Solicitation	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, an IPv6 MLD packet is defined to be any packet that meets all of the following requirements:</p> <ul style="list-style-type: none"> <li>The destination MAC address field is set to a layer 2 multicast address of the form 33:33:FF:XX:XX:XX. This address corresponds to the Solicited Node multicast address where the last three bytes of the destination MAC address are ignored for this filter.</li> <li>The Ethertype field is set to 0x86DD (IPv6).</li> <li>The IPv6 header's Next Header field is set to 58 (ICMPv6).</li> <li>The ICMPv6 header's Message Type field is set to one of the following values: 135</li> </ul> <p>This field is optional.</p> <p>Implementation Note: Enabling of this filter results in receiving all IPv6 neighbor solicitation traffic on this channel. If IPv6 neighbor solicitation traffic for a specific multicast address is of interest, then it is recommended that the MC uses a multicast address filter (configured for the multicast address using the Set MAC Address command) instead of this filter.</p>

Bit Position	Field Description	Value Description
6	LLDP	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, a LLDP packet is defined to be any packet that meets all of the following requirements:</p> <p>The destination MAC address field is set to a layer 2 multicast address of the form 01:80:C2:00:00:00, or 01:80:C2:00:00:03, or 01:80:C2:00:00:0E.</p> <p>The Ethertype field is set to 0x88CC.</p> <p>This field is optional.</p> <p>Implementation Note: Enabling of this filter results in receiving a copy of all LLDP traffic on this channel. If LLDP traffic for a specific LLDP multicast address is of interest, then it is recommended that the MC uses a multicast address filter (configured for the multicast address using the Set MAC Address command) instead of this filter.</p> <p>The intent of this filter is to allow the MC to snoop the received LLDP frame by the port, not to achieve ownership of any contained protocols.</p>
7	mDNSv4	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, a mDNS/IPv4 packet is defined to be any packet that meets all the following requirements:</p> <p>The destination MAC address field is set to a layer 2 multicast address of the form 01:00:5E:00:00:FB.</p> <p>The Ethertype field is set to 0x0800.</p> <p>The IPv4 address is 224.0.0.251.</p> <p>The IPv4 header's Protocol field is set to 17 (UDP).</p> <p>The UDP destination port number is set to 5353.</p> <p>This field is optional.</p>
8	mDNSv6	<p>1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.</p> <p>For the purposes of this specification, a mDNS/IPv6 packet is defined to be any packet that meets all the following requirements:</p> <p>The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:FB. This corresponds to the All Nodes IPv6 multicast address, FF02::FB.</p> <p>The Ethertype field is set to 0x086DD.</p> <p>The IPv6 header's Next Header field is set to 17 (UDP).</p> <p>The UDP destination port number is set to 5353.</p> <p>This field is optional.</p>
31..9	Reserved	None

**8.5.38 Enable Global Multicast Filter response (0x92)**

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Enable Global Multicast Filter command and send a response.

Currently no command-specific reason code is identified for this response (see Table 80).

**Table 80 – Enable Global Multicast Filter response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header

20..23	Checksum			
24..45	Pad			

**8.5.39 Disable Global Multicast Filter command (0x13)**

The Disable Global Multicast Filter command is used to disable global filtering of multicast frames. Upon receiving and processing this command, and regardless of the current state of multicast filtering, the channel shall forward all multicast frames to the Management Controller.

This command shall be implemented on the condition that the channel implementation supports accepting all multicast addresses. An implementation that does not support accepting all multicast addresses shall not implement these commands. Pass-through packets with multicast addresses can still be accepted depending on multicast address filter support provided by the Set MAC Address command. Packets with destination addresses matching multicast filter entries that are set to enabled in the Set MAC Address command are accepted; all others are rejected.

Table 81 illustrates the packet format of the Disable Global Multicast Filter command.

**Table 81 – Disable Global Multicast Filter command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

**8.5.40 Disable Global Multicast Filter response (0x93)**

In the absence of any errors, the channel shall process and respond to the Disable Global Multicast Filter command by sending the response packet shown in Table 82.

Currently no command-specific reason code is identified for this response.

2656

**Table 82 – Disable Global Multicast Filter response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

2657 **8.5.41 Set NC-SI Flow Control command (0x14)**

2658 The Set NC-SI Flow Control command allows the Management Controller to configure [IEEE 802.3](#) pause  
 2659 packet flow control on the NC-SI.

2660 The Set NC-SI Flow Control command is addressed to the package, rather than to a particular channel  
 2661 (that is, the command is sent with a Channel ID where the Package ID subfield matches the ID of the  
 2662 intended package and the Internal Channel ID subfield is set to 0x1F).

2663 The setting of [IEEE 802.3](#) Pause packet flow control on RBT is independent from any arbitration scheme,  
 2664 if any is used.

2665 Table 83 illustrates the packet format of the Set NC-SI Flow Control command.

2666

**Table 83 – Set NC-SI Flow Control command packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Reserved			Flow Control Enable
20..23	Checksum			
24..45	Pad			

2667 Table 84 describes the values for the Flow Control Enable field.

2668

**Table 84 – Values for the Flow Control Enable field (8-bit field)**

Value	Description
0x0	Disables NC-SI flow control
0x1	Enables Network Controller to Management Controller flow control frames (Network Controller generates flow control frames) This field is optional.
0x2	Enables Management Controller to Network Controller flow control frames (Network Controller accepts flow control frames) This field is optional.
0x3	Enables bi-directional flow control frames This field is optional.

Value	Description
0x4..0xFF	Reserved

#### 8.5.42 Set NC-SI Flow Control response (0x94)

The package shall, in the absence of a checksum error or identifier mismatch, always accept the Set NC-SI Flow Control command and send a response (see Table 85).

**Table 85 – Set NC-SI Flow Control response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

Table 86 describes the reason code that is specific to the Set NC-SI Flow Control command.

**Table 86 – Set NC-SI Flow Control command-specific reason code**

Value	Description	Comment
0x1409	Independent transmit and receive enable/disable control is not supported	Returned when the implementation requires that both transmit and receive flow control be enabled and disabled simultaneously

#### 8.5.43 Get Version ID command (0x15)

The Get Version ID command may be used by the Management Controller to request the channel to provide the controller and firmware type and version strings listed in the response payload description.

Table 87 illustrates the packet format of the Get Version ID command.

**Table 87 – Get Version ID command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

#### 8.5.44 Get Version ID Response (0x95)

The channel shall, in the absence of an error, always accept the Get Version ID command and send the response packet shown in Table 88. Currently no command-specific reason code is identified for this response.

NOTE: When multiple Physical Functions are enabled on the channel, the PCI ID that is returned shall be that of the lowest numbered Function on the channel.

**Table 88 – Get Version ID response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	NC-SI Version			
	Major	Minor	Update	Alpha1
24..27	reserved	reserved	reserved	Alpha2
28..31	Firmware Name String (11-08)			
32..35	Firmware Name String (07-04)			
36..39	Firmware Name String (03-00)			
40..43	Firmware Version			
	MS-byte (3)	Byte (2)	Byte (1)	LS-byte (0)
44..47	PCI DID		PCI VID	
48..51	PCI SSID		PCI SVID	
52..55	Manufacturer ID (IANA)			
56..59	Checksum			

#### 8.5.44.1 NC-SI Version encoding

The NC-SI Version field holds the version number of the NC-SI specification with which the controller is compatible. The version field shall be encoded as follows:

- The 'major', 'minor', and 'update' bytes are BCD-encoded, and each byte holds two BCD digits.
- The 'alpha' byte holds an optional alphanumeric character extension that is encoded using the ISO/IEC 8859-1 Character Set.
- The semantics of these fields follow the semantics specified in [DSP4014](#).
- The value 0x00 in the Alpha1 or Alpha2 fields means that the corresponding alpha field is not used. The Alpha1 field shall be used first.
- The value 0xF in the most-significant nibble of a BCD-encoded value indicates that the most-significant nibble should be ignored and the overall field treated as a single digit value.
- A value of 0xFF in the update field indicates that the entire field is not present. 0xFF is not allowed as a value for the major or minor fields.

EXAMPLE: Version 3.7.10a → 0xF3F7106100  
 Version 10.01.7 → 0x1001F70000  
 Version 3.1 → 0xF3F1FF0000  
 Version 1.0a → 0xF1F0FF4100  
 Version 1.0ab → 0xF1F0FF4142 (Alpha1 = 0x41, Alpha2 = 0x42)

#### 2705 8.5.44.2 Firmware Name encoding

2706 The Firmware Name String shall be encoded using the ISO/IEC 8859-1 Character Set. Strings are left-  
 2707 justified where the leftmost character of the string occupies the most-significant byte position of the  
 2708 Firmware Name String field, and characters are populated starting from that byte position. The string is  
 2709 null terminated if the string is smaller than the field size. That is, the delimiter value, 0x00, follows the last  
 2710 character of the string if the string occupies fewer bytes than the size of the field allows. A delimiter is not  
 2711 required if the string occupies the full size of the field. Bytes following the delimiter (if any) should be  
 2712 ignored and can be any value.

#### 2713 8.5.44.3 Firmware Version encoding

2714 To facilitate a common way of representing and displaying firmware version numbers across different  
 2715 vendors, each byte is hexadecimal encoded where each byte in the field holds two hexadecimal digits.  
 2716 The Firmware Version field shall be encoded as follows. The bytes are collected into a single 32-bit field  
 2717 where each byte represents a different 'point number' of the overall version. The selection of values that  
 2718 represent a particular version of firmware is specific to the Network Controller vendor.

2719 Software displaying these numbers should not suppress leading zeros, which should help avoid user  
 2720 confusion in interpreting the numbers. For example, consider the two values 0x05 and 0x31.  
 2721 Numerically, the byte 0x31 is greater than 0x05, but if leading zeros were incorrectly suppressed, the two  
 2722 displayed values would be ".5" and ".31", respectively, and a user would generally interpret 0.5 as  
 2723 representing a greater value than 0.31 instead of 0.05 being smaller than 0.31. Similarly, if leading zeros  
 2724 were incorrectly suppressed, the value 0x01 and 0x10 would be displayed as 0.1 and 0.10, which could  
 2725 potentially be misinterpreted as representing the same version instead of 0.01 and 0.10 versions.

2726 EXAMPLE: 0x00030217 → Version 00.03.02.17  
 2727 0x010100A0 → Version 01.01.00.A0

#### 2728 8.5.44.4 PCI ID fields

2729 These fields (PCI DID, PCI VID, PCI SSID, PCI SVID) hold the PCI ID information for the Network  
 2730 Controller when the Network Controller incorporates a PCI or PCI Express™ interface that provides a  
 2731 host network interface connection that is shared with the NC-SI connection to the network.

2732 If this field is not used, the values shall all be set to zeros (0000h). Otherwise, the fields shall hold the  
 2733 PCI ID information for the host interface as defined by the version of the PCI/PCI Express™ specification  
 2734 to which the device's interface was designed.

2735 If multiple partitions are enabled on the channel, the values should represent the PCI ID of the lowest  
 2736 Function number assigned to the channel by the Set PF Assignment command (0x28).

#### 2737 8.5.44.5 Manufacturer ID (IANA) field

2738 The Manufacturer ID holds the [IANA Enterprise Number](#) for the manufacturer of the Network Controller as  
 2739 a 32-bit binary number. If the field is unused, the value shall be set to 0xFFFFFFFF.

### 8.5.45 Get Capabilities command (0x16)

The Get Capabilities command is used to discover additional optional functions supported by the channel, such as the number of unicast/multicast addresses supported, the amount of buffering in bytes available for packets bound for the Management Controller, and so on.

Table 89 illustrates the packet format for the Get Capabilities command.

**Table 89 – Get Capabilities command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

### 8.5.46 Get Capabilities response (0x96)

In the absence of any errors, the channel shall process and respond to the Get Capabilities Command and send the response packet shown in Table 90. Currently no command-specific reason code is identified for this response.

**Table 90 – Get Capabilities response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Capabilities Flags			
24..27	Broadcast Packet Filter Capabilities			
28..31	Multicast Packet Filter Capabilities			
32..35	Buffering Capability			
36..39	AEN Control Support			
40..43	VLAN Filter Count	Mixed Filter Count	Multicast Filter Count	Unicast Filter Count
44..47	Reserved		VLAN Mode Support	Channel Count
48..51	Checksum			

#### 8.5.46.1 Capabilities Flags field

The Capabilities Flags field indicates which optional features of this specification the channel supports, as described in Table 91.

2754

Table 91 – Capabilities Flags bit definitions

Bit Position	Field Description	Value Description
0	Hardware Arbitration Capability	0b = Hardware arbitration capability is not supported by the package. 1b = Hardware arbitration capability is supported by the package.
1	Host NC Driver Status	0b = Host NC Driver Indication status is not supported. 1b = Host NC Driver Indication status is supported. See Table 53 for the definition of Host NC Driver Indication Status.
2	Network Controller to Management Controller Flow Control Support	0b = Network Controller to Management Controller flow control is not supported. 1b = Network Controller to Management Controller flow control is supported.
3	Management Controller to Network Controller Flow Control Support	0b = Management Controller to Network Controller flow control is not supported. 1b = Management Controller to Network Controller flow control is supported.
4	All multicast addresses support	0b = The channel cannot accept all multicast addresses. The channel does not support enable/disable global multicast commands. 1b = The channel can accept all multicast addresses. The channel supports enable/disable global multicast commands.
6..5	Hardware Arbitration Implementation Status	00b = Unknown 01b = Hardware arbitration capability is not implemented for the package on the given system. 10b = Hardware arbitration capability is implemented for the package on the given system. 11b = Reserved.
7	Thermal shutdown Implementation Status	0b = The thermal self-shutdown capability is not supported by the channel (package). 1b = The thermal self-shutdown capability is supported by the channel (package).
8	Delayed Response Support	0b = Delayed response operation and signaling is not supported by the channel (package). 1b = Delayed response operation and signaling is supported by the channel (package).
9..31	Reserved	Reserved

#### 2755 8.5.46.2 Broadcast Packet Filter Capabilities field

2756 The Broadcast Packet Filter Capabilities field defines the optional broadcast packet filtering capabilities  
 2757 that the channel supports. The bit definitions for this field correspond directly with the bit definitions for the  
 2758 Broadcast Packet Filter Settings field defined for the Enable Broadcast Filter command in Table 74. A bit  
 2759 set to 1 indicates that the channel supports the filter associated with that bit position; otherwise, the  
 2760 channel does not support that filter.

### 2761 8.5.46.3 Multicast Packet Filter Capabilities field

2762 The Multicast Packet Filter Capabilities field defines the optional multicast packet filtering capabilities that  
 2763 the channel supports. The bit definitions for this field correspond directly with the bit definitions for the  
 2764 Multicast Packet Filter Settings field defined for the Enable Global Multicast Filter command in Table 79.  
 2765 A bit set to 1 indicates that the channel supports the filter associated with that bit position; otherwise, the  
 2766 channel does not support that filter.

### 2767 8.5.46.4 Buffering Capability field

2768 The Buffering Capability field defines the amount of buffering in bytes that the channel provides for  
 2769 inbound packets destined for the Management Controller. The Management Controller may make use of  
 2770 this value in software-based Device Selection implementations to determine the relative time for which a  
 2771 specific channel may be disabled before it is likely to start dropping packets. A value of 0 indicates that  
 2772 the amount of buffering is unspecified.

### 2773 8.5.46.5 AEN Control Support field

2774 The AEN Control Support field indicates various standard AENs supported by the implementation. The  
 2775 format of the field is shown in Table 43.

### 2776 8.5.46.6 VLAN Filter Count field

2777 The VLAN Filter Count field indicates the number of VLAN filters, up to 15, that the channel supports, as  
 2778 defined by the Set VLAN Filter command.

### 2779 8.5.46.7 Mixed, Multicast, and Unicast Filter Count fields

2780 The Mixed Filter Count field indicates the number of mixed address filters that the channel supports. A  
 2781 mixed address filter can be used to filter on specific unicast or multicast MAC addresses.

2782 The Multicast Filter Count field indicates the number of multicast MAC address filters that the channel  
 2783 supports.

2784 The Unicast Filter Count field indicates the number of unicast MAC address filters that the channel  
 2785 supports.

2786 The channel is required to support at least one unicast or mixed filter, such that at least one unicast MAC  
 2787 address can be configured on the interface. The total number of unicast, multicast, and mixed filters shall  
 2788 not exceed 8.

### 2789 8.5.46.8 VLAN Mode Support field

2790 The VLAN Mode Support field indicates various modes supported by the implementation. The format of  
 2791 field is defined in Table 92.

2792 **Table 92 – VLAN Mode Support bit definitions**

Bit Position	Field Description	Value Description
0	VLAN only	1 = VLAN shall be supported in the implementation.
1	VLAN + non-VLAN	0 = Filtering 'VLAN + non-VLAN' traffic is not supported in the implementation. 1 = Filtering 'VLAN + non-VLAN' traffic is supported in the implementation.

Bit Position	Field Description	Value Description
2	Any VLAN + non-VLAN	0 = Filtering 'Any VLAN + non-VLAN' traffic is not supported in the implementation. 1 = Filtering 'Any VLAN + non-VLAN' traffic is supported in the implementation.
3..7	Reserved	0

#### 2793 8.5.46.9 Channel Count field

2794 The Channel Count field indicates the number of channels supported by the Network Controller.

#### 2795 8.5.47 Get Parameters command (0x17)

2796 The Get Parameters command can be used by the Management Controller to request that the channel  
2797 send the Management Controller a copy of all of the currently stored parameter settings that have been  
2798 put into effect by the Management Controller, plus "other" Host/Channel parameter values that may be  
2799 added to the Get Parameters Response Payload.

2800 Table 93 illustrates the packet format for the Get Parameters command.

2801 **Table 93 – Get Parameters command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

#### 2802 8.5.48 Get Parameters response (0x97)

2803 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get  
2804 Parameters command and send a response. As shown in Table 94, each parameter shall return the value  
2805 that was set by the Management Controller. If the parameter is not supported, 0 is returned. Currently no  
2806 command-specific reason code is identified for this response.

2807 The payload length of this response packet will vary according to how many MAC address filters or VLAN  
2808 filters the channel supports. All supported MAC addresses are returned at the end of the packet, without  
2809 any intervening padding between MAC addresses.

2810 MAC addresses are returned in the following order: unicast filtered addresses first, followed by multicast  
2811 filtered addresses, followed by mixed filtered addresses, with the number of each corresponding to those  
2812 reported through the Get Capabilities command. For example, if the interface reports four unicast filters,  
2813 two multicast filters, and two mixed filters, then MAC addresses 1 through 4 are those currently  
2814 configured through the interface's unicast filters, MAC addresses 5 and 6 are those configured through  
2815 the multicast filters, and 7 and 8 are those configured through the mixed filters. Similarly, if the interface  
2816 reports two unicast filters, no multicast filters, and six mixed filters, then MAC addresses 1 and 2 are  
2817 those currently configured through the unicast filters, and 3 through 8 are those configured through the  
2818 mixed filters.

2819

**Table 94 – Get Parameters response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00

52..55 <sup>a</sup>	MAC Address 1 byte 1	MAC Address 1 byte 0	MAC Address 2 byte 5	MAC Address 2 byte 4
56..59	MAC Address 2 byte 3	MAC Address 2 byte 2	MAC Address 2 byte 1	MAC Address 2 byte 0
variable	...			
	VLAN Tag 1		VLAN Tag 2	
	...			
	...		Pad (if needed)	
	Checksum			

<sup>a</sup> Variable fields can start at this byte offset.

2820 Table 95 lists the parameters for which values are returned in this response packet.

2821

**Table 95 – Get Parameters data definition**

Parameter Field Name	Description
MAC Address Count	The number of MAC addresses supported by the channel
MAC Address Flags	The enable/disable state for each supported MAC address See Table 96.
VLAN Tag Count	The number of VLAN Tags supported by the channel
VLAN Tag Flags	The enable/disable state for each supported VLAN Tag See Table 97.
Link Settings	The 32-bit Link Settings value as defined in the Set Link command. See Table 46.
Broadcast Packet Filter Settings	The current 32-bit Broadcast Packet Filter Settings value
Configuration Flags	See Table 98.

Parameter Field Name	Description
VLAN Mode	See Table 63.
Flow Control Enable	See Table 84.
AEN Control	See Table 43.
MAC Address 1..8	The current contents of up to eight 6-byte MAC address filter values.
VLAN Tag 1..15	The current contents of up to 15 16-bit VLAN Tag filter values
...	

2822 The format of the MAC Address Flags field is defined in Table 96.

2823 **Table 96 – MAC Address Flags bit definitions**

Bit Position	Field Description	Value Description
0	MAC address 1 status	0b = Default or unsupported or disabled 1b = Enabled
1	MAC address 2 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled
2	MAC address 3 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled
...	...	...
7	MAC address 8 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled

2824 The format of the VLAN Tag Flags field is defined in Table 97.

2825 **Table 97 – VLAN Tag Flags bit definitions**

Bit Position	Field Description	Value Description
0	VLAN Tag 1 status	0b = Default or unsupported or disabled 1b = Enabled
1	VLAN Tag 2 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled
2	VLAN Tag 3 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled
...	...	...
14	VLAN Tag 15 status, or Reserved	0b = Default or unsupported or disabled 1b = Enabled

2826 The format of the Configuration Flags field is defined in Table 98.

2827

**Table 98 – Configuration Flags bit definitions**

Bit Position	Field Description	Value Description
0	Broadcast Packet Filter status	0b = Disabled 1b = Enabled
1	Channel Enabled	0b = Disabled 1b = Enabled
2	Channel Network TX Enabled	0b = Disabled 1b = Enabled
3	Global Multicast Packet Filter Status	0b = Disabled 1b = Enabled
4..31	Reserved	Reserved

**2828 8.5.49 Get Controller Packet Statistics command (0x18)**

2829 The Get Controller Packet Statistics command may be used by the Management Controller to request a  
 2830 copy of the aggregated Ethernet packet statistics that the channel maintains for its external interface to  
 2831 the LAN network. The statistics are an aggregation of statistics for both the host side traffic and the NC-SI  
 2832 Pass-through traffic.

2833

**Table 99 – Get Controller Packet Statistics command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

**2834 8.5.50 Get Controller Packet Statistics response (0x98)**

2835 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get  
 2836 Controller Packet Statistics command and send the response packet shown in Table 100.

2837 The Get Controller Packet Statistics Response frame contains a set of Ethernet statistics counters that  
 2838 monitor the LAN traffic in the Network Controller. Implementation of the counters listed in Table 101 is  
 2839 optional. The Network Controller shall return any unsupported counter with a value of 0xFFFFFFFF for  
 2840 32-bit counters and 0xFFFFFFFFFFFFFFFF for 64-bit counters.

2841

Table 100 – Get Controller Packet Statistics response packet format

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header

2842

Table 101 – Get Controller Packet Statistics counters

Counter Number	Name	Meaning
0	Total Bytes Received	Counts the number of bytes received
1	Total Bytes Transmitted	Counts the number of bytes transmitted
2	Total Unicast Packets Received	Counts the number of good (FCS valid) packets received that passed L2 filtering by a specific MAC address
3	Total Multicast Packets Received	Counts the number of good (FCS valid) multicast packets received
4	Total Broadcast Packets Received	Counts the number of good (FCS valid) broadcast packets received
5	Total Unicast Packets Transmitted	Counts the number of good (FCS valid) packets transmitted that passed L2 filtering by a specific MAC address
6	Total Multicast Packets Transmitted	Counts the number of good (FCS valid) multicast packets transmitted
7	Total Broadcast Packets Transmitted	Counts the number of good (FCS valid) broadcast packets transmitted
8	FCS Receive Errors	Counts the number of receive packets with FCS errors
9	Alignment Errors	Counts the number of receive packets with alignment errors
10	False Carrier Detections	Counts the false carrier errors reported by the PHY
11	Runt Packets Received	Counts the number of received frames that passed address filtering, were less than minimum size (64 bytes from <Destination Address> through <FCS>, inclusively), and had a valid FCS

Counter Number	Name	Meaning
12	Jabber Packets Received	Counts the number of received frames that passed address filtering, were greater than the maximum size, and had a valid FCS
13	Pause XON Frames Received	Counts the number of XON packets received from the network
14	Pause XOFF Frames Received	Counts the number of XOFF packets received from the network
15	Pause XOFF Frames Transmitted	Counts the number of XON packets transmitted to the network
16	Pause XOFF Frames Transmitted	Counts the number of XOFF packets transmitted to the network
17	Single Collision Transmit Frames	Counts the number of times that a successfully transmitted packet encountered a single collision
18	Multiple Collision Transmit Frames	Counts the number of times that a transmitted packet encountered more than one collision but fewer than 16
19	Late Collision Frames	Counts the number of collisions that occurred after one slot time (defined by <a href="#">IEEE 802.3</a> )
20	Excessive Collision Frames	Counts the number of times that 16 or more collisions occurred on a single transmit packet
21	Control Frames Received	Counts the number of MAC control frames received that are <i>not</i> XON or XOFF flow control frames
22	64 Byte Frames Received	Counts the number of good packets received that are exactly 64 bytes (from <Destination Address> through <FCS>, inclusively) in length
23	65–127 Byte Frames Received	Counts the number of good packets received that are 65–127 bytes (from <Destination Address> through <FCS>, inclusively) in length
24	128–255 Byte Frames Received	Counts the number of good packets received that are 128–255 bytes (from <Destination Address> through <FCS>, inclusively) in length
25	256–511 Byte Frames Received	Counts the number of good packets received that are 256–511 bytes (from <Destination Address> through <FCS>, inclusively) in length
26	512–1023 Byte Frames Received	Counts the number of good packets received that are 512–1023 bytes (from <Destination Address> through <FCS>, inclusively) in length
27	1024–1522 Byte Frames Received	Counts the number of good packets received that are 1024–1522 bytes (from <Destination Address> through <FCS>, inclusively) in length
28	1523–9022 Byte Frames Received	Counts the number of received frames that passed address filtering and were greater than 1523 bytes in length
29	64 Byte Frames Transmitted	Counts the number of good packets transmitted that are exactly 64 bytes (from <Destination Address> through <FCS>, inclusively) in length

Counter Number	Name	Meaning
30	65–127 Byte Frames Transmitted	Counts the number of good packets transmitted that are 65–127 bytes (from <Destination Address> through <FCS>, inclusively) in length
31	128–255 Byte Frames Transmitted	Counts the number of good packets transmitted that are 128–255 bytes (from <Destination Address> through <FCS>, inclusively) in length
32	256–511 Byte Frames Transmitted	Counts the number of good packets transmitted that are 256–511 bytes (from <Destination Address> through <FCS>, inclusively) in length
33	512–1023 Byte Frames Transmitted	Counts the number of good packets transmitted that are 512–1023 bytes (from <Destination Address> through <FCS>, inclusively) in length
34	1024–1522 Byte Frames Transmitted	Counts the number of good packets transmitted that are 1024–1522 bytes (from <Destination Address> through <FCS>, inclusively) in length
35	1523–9022 Byte Frames Transmitted	Counts the number of transmitted frames that passed address filtering and were greater than 1523 in length
36	Valid Bytes Received	Counts the bytes received in all packets that did not manifest any type of error
37	Error Runt Packets Received	Counts the number of invalid frames that were less than the minimum size (64 bytes from <Destination Address> through <FCS>, inclusively)
38	Error Jabber Packets Received	Counts Jabber packets, which are defined as packets that exceed the programmed MTU size <i>and</i> have a bad FCS value

2843 The Network Controller shall also indicate in the Counters Cleared from Last Read fields whether the  
 2844 corresponding field has been cleared by means other than NC-SI (possibly by the host) since it was last  
 2845 read by means of the NC-SI. Counting shall resume from 0 after a counter has been cleared. The  
 2846 Counters Cleared from Last Read field's format is shown in Table 102.

2847 Currently no command-specific reason code is identified for this response.

2848 **Table 102 – Counters Cleared from Last Read Fields format**

Field	Bits	Mapped to Counter Numbers
MS Bits	0..6	32..38
	7..31	Reserved
LS Bits	0..31	0..31

2849 Implementation Note: The Get Controller Packet Statistics response contains the following counters related to flow  
 2850 control: Pause XON Frames Received, Pause XOFF Frames Received, Pause XON Frames  
 2851 Transmitted, and Pause XOFF Frames Transmitted. An implementation can optionally include  
 2852 Priority-Based Flow Control (PFC) packets in these counters.

### 2853 8.5.51 Get NC-SI Statistics command (0x19)

2854 In addition to the packet statistics accumulated on the LAN network interface, the channel separately  
 2855 accumulates a variety of NC-SI specific packet statistics for the channel. The Get NC-SI Statistics

2856 command may be used by the Management Controller to request that the channel send a copy of all  
 2857 current NC-SI packet statistic values for the channel. The implementation may or may not include  
 2858 statistics for commands that are directed to the package.

2859 Table 103 illustrates the packet format of the Get NC-SI Statistics command.

2860 **Table 103 – Get NC-SI Statistics command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

### 2861 8.5.52 Get NC-SI Statistics response (0x99)

2862 In the absence of any error, the channel shall process and respond to the Get NC-SI Statistics command  
 2863 by sending the response packet and payload shown in Table 104.

2864 **Table 104 – Get NC-SI Statistics response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	NC-SI Commands Received			
24..27	NC-SI Control Packets Dropped			
28..31	NC-SI Command Type Errors			
32..35	NC-SI Command Checksum Errors			
36..39	NC-SI Receive Packets			
40..43	NC-SI Transmit Packets			
44..47	AENs Sent			
48..51	Checksum			

2865 The Get NC-SI Statistics Response frame contains a set of statistics counters that monitor the NC-SI  
 2866 traffic in the Network Controller. Counters that are supported shall be reset to 0x0 when entering the  
 2867 Initial State and after being read. Implementation of the counters shown in Table 105 is optional. The  
 2868 Network Controller shall return any unsupported counter with a value of 0xFFFFFFFF. Counters may  
 2869 wraparound or stop if they reach 0xFFFFFFFF. It is vendor-specific how NC-SI commands that are sent  
 2870 to the package ID are included in the NC-SI statistics.

2871 Currently no command-specific reason code is identified for this response.

2872 **Table 105 – Get NC-SI Statistics counters**

Counter Number	Name	Meaning
1	NC-SI Commands Received	For packets that are not dropped, this field returns the number of NC-SI Control Packets received and identified as NC-SI commands.
2	NC-SI Control Packets Dropped	Counts the number of NC-SI Control Packets that were received and dropped (Packets with correct FCS and Ethertype, but are dropped for one of the other reasons listed in clause 6.9.2.1). NC-SI Control Packets that were dropped because the channel ID was not valid may not be included in this statistics counter.
3	NC-SI Unsupported Commands Received	Counts the number of NC-SI command packets that were received but are not supported. (Network controller responded to the command with a Command Unsupported response code).
4	NC-SI Command Checksum Errors	Counts the number of NC-SI Control Packets that were received but dropped because of an invalid checksum (if checksum is provided and checksum validation is supported by the channel)
5	NC-SI Receive Packets	Counts the total number of NC-SI Control Packets received. This count is the sum of NC-SI Commands Received and NC-SI Control Packets Dropped.
6	NC-SI Transmit Packets	Counts the total number of NC-SI Control Packets transmitted to the Management Controller. This count is the sum of NC-SI responses sent and AENs sent.
7	AENs Sent	Counts the total number of AEN packets transmitted to the Management Controller

2873 **8.5.53 Get NC-SI Pass-through Statistics command (0x1A)**

2874 The Get NC-SI Pass-through Statistics command may be used by the Management Controller to request  
 2875 that the channel send a copy of all current NC-SI Pass-through packet statistic values.

2876 Table 106 illustrates the packet format of the Get NC-SI Pass-through Statistics command.

2877 **Table 106 – Get NC-SI Pass-through Statistics command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

#### 2878 8.5.54 Get NC-SI Pass-through Statistics response (0x9A)

2879 In the absence of any error, the channel shall process and respond to the Get NC-SI Pass-through  
2880 Statistics command by sending the response packet and payload shown in Table 107.

2881 **Table 107 – Get NC-SI Pass-through Statistics response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..27	Pass-through TX Packets Received on NC-SI Interface (Management Controller to Network Controller)			
28..31	Pass-through TX Packets Dropped			
32..35	Pass-through TX Packet Channel State Errors			
36..39	Pass-through TX Packet Undersized Errors			
40..43	Pass-through TX Packet Oversized Errors			
44..47	Pass-through RX Packets Received on LAN Interface			
48..51	Total Pass-through RX Packets Dropped			
52..55	Pass-through RX Packet Channel State Errors			
56..59	Pass-through RX Packet Undersized Errors			
60..63	Pass-through RX Packet Oversized Errors			
64..67	Checksum			

2882 The Get NC-SI Statistics Response frame contains a set of statistics counters that monitor the NC-SI  
2883 Pass-through traffic in the Network Controller. Supported counters shall be reset to 0x0 when entering  
2884 the Initial State and after being read. Implementation of the counters shown in Table 108 is optional. The  
2885 Network Controller shall return any unsupported counter with a value of 0xFFFFFFFF for 32-bit counters  
2886 and 0xFFFFFFFFFFFFFFFF for 64-bit counters. Counters may wraparound or stop if they reach  
2887 0xFFFFFFFFFE for 32-bit counters and 0xFFFFFFFFFFFFFFFFFE for 64-bit counters.

2888 **Table 108 – Get NC-SI Pass-through Statistics counters**

Counter Number	Name	Meaning
1	Total Pass-through TX Packets Received (Management Controller to Channel)	Counts the number of Pass-through packets forwarded by the channel to the LAN
2	Total Pass-through TX Packets Dropped (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were dropped by the Network Controller
3	Pass-through TX Packet Channel State Errors (Management Controller to Channel)	Counts the number of egress management packets (Management Controller to Network Controller) that were dropped because the channel was in the disabled state when the packet was received

Counter Number	Name	Meaning
4	Pass-through TX Packet Undersized Errors (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were undersized (under 64 bytes, including FCS)
5	Pass-through TX Packet Oversized Errors (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were oversized (over 1522 bytes, including FCS)
6	Total Pass-through RX Packets Received on the LAN Interface (LAN to Channel)	Counts the number of Pass-through packets that were received on the LAN interface of the channel. This counter does not necessarily count the number of packets that were transmitted to the Management Controller, because some of the packets might have been dropped due to RX queue overflow.
7	Total Pass-through RX Packets Dropped (LAN to Channel)	Counts the number of Pass-through packets that were received on the LAN interface of the channel but were dropped and not transmitted to the Management Controller
8	Pass-through RX Packet Channel State Errors (LAN to Channel)	Counts the number of ingress management packets (channel to Management Controller) that were dropped because the channel was in the disabled state when the packet was received. The NC may also count packets that were dropped because the package was in the deselected state.
9	Pass-through RX Packet Undersized Errors (LAN to Channel)	Counts the number of Pass-through packets from the LAN that were undersized (under 64 bytes, including FCS)
10	Pass-through RX Packet Oversized Errors (LAN to Channel)	Counts the number of Pass-through packets from the LAN that were oversized (over 1522 bytes, including FCS)

2889 Currently no command-specific reason code is identified for this response.

#### 2890 8.5.55 Get Package Status command (0x1B)

2891 The Get Package Status command provides a way for a Management Controller to explicitly query the  
 2892 status of a package. The Get Package Status command is addressed to the package, rather than to a  
 2893 particular channel (that is, the command is sent with a Channel ID where the Package ID subfield  
 2894 matches the ID of the intended package, and the Internal Channel ID subfield is set to 0x1F).

2895 Table 109 illustrates the packet format of the Get Package Status command.

2896 **Table 109 – Get Package Status packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
20..23	Checksum			
24..45	Pad			

### 2897 8.5.56 Get Package Status response (0x9B)

2898 In the absence of any errors, the package shall process and respond to the Get Package Status  
2899 Command and send the response packet shown in Table 110.

2900 Currently no command-specific reason code is identified for this response.

2901 **Table 110 – Get Package Status response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Package Status			
24..27	Checksum			
28..45	Pad			

2902 **Table 111 – Package Status field bit definitions**

Bit Position	Field Description	Value Description
0	Hardware Arbitration Status	0b = Hardware arbitration is non-operational (inactive) or unsupported.  NOTE: This means that hardware arbitration tokens are not flowing through this NC.  1b = Hardware arbitration is supported, active, and implemented for the package on the given system.
1	Delayed Response Status	0b = Delayed Response handling is disabled. 1b = Delayed Response handling is enabled.
31.. 2	Reserved	Reserved

### 2903 8.5.57 Get NC Capabilities and Settings command (0x25)

2904 The Get NC Capabilities and Settings command is sent only as a package command. It is used to  
2905 discover the supported architectural and currently configured (active) parameters of the NC.

2906 Table 112 illustrates the packet format for the Get NC Capabilities and Settings command.

2907 **Table 112 – Get NC Capabilities and Settings command packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

### 2908 8.5.58 Get NC Capabilities and Settings response (0xA5)

2909 In the absence of any errors, the package shall process and respond to the Get NC Capabilities and  
2910 Settings Command and send the response packet shown in Table 113.

2911 Currently no command-specific reason code is identified for this response.

2912 **Table 113 - Get NC Capabilities and Settings response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Max Ports	Enabled Ports	Max PCI Endpoints	Enabled PCI Endpoints
24..27	Max PFs	Enabled PFs	Max VFs	
28..31	Fabrics	Enabled Fabrics	Other Capabilities	
32..35	Checksum			
36..45	Pad			

#### 2913 8.5.58.1 Max Ports field

2914 The Max Ports field indicates the maximum number of network ports that can be supported by the  
2915 implementation (uint8).

#### 2916 8.5.58.2 Enabled Ports field

2917 The Enabled Ports field indicates the current number of network ports that are currently configured  
2918 (uint8).

#### 2919 8.5.58.3 Max PCI Endpoints field

2920 The Max PCI Endpoints field indicates the maximum number of PCI Endpoints that can be supported by  
2921 the implementation (uint8).

#### 2922 8.5.58.4 Enabled PCI Endpoints field

2923 The Enabled PCI Endpoints field indicates the current number of PCI Endpoints that are currently  
2924 configured (uint8).

#### 2925 8.5.58.5 Max PFs field

2926 The Max PFs field indicates the maximum number of PCI Physical Functions that can be supported by  
2927 the implementation (uint8).

#### 2928 8.5.58.6 Enabled PFs field

2929 The Enabled PFs field indicates the current number of PCI Physical Functions that are currently  
2930 configured (uint8).

2931 **8.5.58.7 Max VFs field**

2932 The Max VFs field indicates the maximum number of PCI Virtual Functions that can be supported by the  
 2933 implementation (uint8).

2934 **8.5.58.8 Fabrics field**

2935 The Fabrics field indicates the network fabrics that can be supported by the implementation.

2936 **Table 114 – Fabrics field bit definitions**

Bit Position	Field Description	Value Description
0	Ethernet	0b0 = Ethernet Fabric is not supported 0b1 = Ethernet Fabric is supported
1	Fibre Channel	0b0 = Fibre Channel Fabric is not supported 0b1 = Fibre Channel Fabric is supported
2	InfiniBand	0b0 = InfiniBand Fabric is not supported 0b1 = InfiniBand Fabric is supported
3..7	Reserved	Reserved

2937 **8.5.58.9 Enabled Fabrics field**

2938 The Enabled Fabrics field indicates the currently configured fabrics.

2939 **Table 115 – Enabled Fabrics field bit definitions**

Bit Position	Field Description	Value Description
0	Ethernet	0b0 = Ethernet Fabric is not enabled 0b1 = Ethernet Fabric is enabled
1	Fibre Channel	0b0 = Fibre Channel Fabric is not enabled 0b1 = Fibre Channel Fabric is enabled
2	InfiniBand	0b0 = InfiniBand Fabric is not enabled 0b1 = InfiniBand Fabric is enabled
3..7	Reserved	Reserved

2940 **8.5.58.10 Other Capabilities field**

2941 The Other Capabilities field indicates which features of this specification the NC supports, as described in  
 2942 Table 116.

2943 **Table 116 – Capabilities Flags bit definitions**

Bit Position	Field Description	Value Description
0	VF allocation	0b = The Max VFs field is interpreted as per port 1b = The Max VFs field is interpreted as per device
1	Enabled Ports	0b = The number of Enabled Ports is fixed 1b = The number of Enabled Ports is programmable

Bit Position	Field Description	Value Description
2	Enabled PCIe Endpoints	0b = The number of Enabled PCIe Endpoints is fixed 1b = The number of Enabled PCIe Endpoints is programmable
3	Enabled PFs	0b = The number of Enabled PFs is fixed 1b = The number of Enabled PFs is programmable
4..15	Reserved	Reserved

### 2944 8.5.59 Set NC Configuration command (0x26)

2945 The Set NC Configuration command allows the Management Controller to configure the number of active  
 2946 Physical functions and PCI (host) and network interfaces, where allowed (generally if the reported max  
 2947 value of the respective entity is greater than one). The values (programmed or fixed) are used in the PF  
 2948 Assignment command where the associations are made between the physical ports, partitions and host  
 2949 buses. If the implementation or controller architecture does not allow any configuration of these  
 2950 parameters, this command shall not be implemented.

2951 The values configured by this command are held by the NC and only take effect at the next PCI reset.

2952 The Set NC Configuration command is addressed to the package, rather than to a channel (that is, the  
 2953 command is sent with a Channel ID where the Package ID subfield matches the ID of the intended  
 2954 package and the Internal Channel ID subfield is set to 0x1F).

2955 Table 117 illustrates the packet format of the Set NC Configuration command.

2956 **Table 117 – Set NC Configuration command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Enable Ports	Enable PCIe Endpoints	Enable PFs	Reserved
20..23	Checksum			
24..45	Pad			

#### 2957 8.5.59.1 Enable Ports field

2958 The Enable Ports field (uint8) indicates the number of network ports to be enabled at the next PCI reset.

#### 2959 8.5.59.2 Enable PCI Endpoints field

2960 The Enable PCI Endpoints field (uint8) indicates the number of PCI Endpoints to be enabled at the next  
 2961 PCI reset. In some implementation architectures this is not settable by NC-SI; in those cases this field  
 2962 becomes read-only and the value is ignored.

#### 2963 8.5.59.3 Enable PFs field

2964 The Enable PFs field (uint8) indicates the number of PCI Physical Functions to be enabled at the next  
 2965 PCI reset.

**8.5.60 Set NC Configuration response ( 0xA6 )**

The package shall, in the absence of a checksum error or identifier mismatch, always accept the Set NC Configuration command and send a response (see Table 118).

**Table 118 – Set NC Configuration response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

**8.5.61 Get PF Assignment command ( 0x27 )**

The Get PF Assignment command is a Package command that allows the Management controller to receive the list of PCI Physical Functions (partitions) currently assigned to channels in the package, their enablement state and conditionally what PCI Endpoint they are assigned to if the NC supports multiple host interfaces.

See the Set PF Assignment command description for additional information.

Table 119 illustrates the packet format of the Get PF Assignment Command.

**Table 119 – Get PF Assignment Command Packet Format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

**8.5.62 Get PF Assignment Response ( 0xA7 )**

In the absence of any errors, the channel shall process and respond to the Get PF Assignment Command and send the response packet shown in the table below.

NOTE: Braces {} denote fields that depend on device capabilities.

**Table 120 – Get PF Assignment Response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Channel 0 Function Assignment bitmap			
24..27	{Channel 1 Function Assignment bitmap}			
	...			

Bytes	Bits			
	31..24	23..16	15..08	07..00
	{Channel <i>c</i> -1 Function Assignment bitmap}			
	Function - Port Association			
	Function Enablement bitmap			
	{PCIe Endpoint 0 Function Assignment bitmap}			
	{PCIe Endpoint 1 Function Assignment bitmap}			
	...			
	{PCIe Endpoint <i>b</i> -1 Function Assignment bitmap}			
	Checksum			
	Pad			

### 2983 8.5.62.1 Channel *c* Function Assignment bitmap fields

2984 The number of Channel Function Assignment bitmaps returned in the response is equal to 'c', the number  
 2985 returned in the Get NC Capabilities and Settings Command Enabled Ports field. The Channel *c* Function  
 2986 Assignment bitmaps are 32-bit fields in which each bit position corresponds to a PCI physical function in  
 2987 the NC on the specified channel. If the physical function is assigned to the *c*<sup>th</sup> channel, even if it not  
 2988 currently enabled, the bit value shall be set to 1b; otherwise, the bit is set to 0b.

2989 **Table 121 – Channel *c* Function Assignment bitmap field**

Bit Position	Field Description	Value Description
0	F0 status	0b = F0 is not assigned on the channel. 1b = F0 is assigned on the channel.
1	F1 status	0b = F1 is not assigned on the channel. 1b = F1 is assigned on the channel.
...	...	...
15	F15 status	0b = F15 is not assigned on the channel. 1b = F15 is assigned on the channel

### 2990 8.5.62.2 Function Port Association bitmap field

2991 The Function Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical  
 2992 function in the device. Unused bits are Reserved.

2993 **Table 122 – Function Port Association bitmap field**

Bit Position	Field Description	Value Description
0	F0 association	0b = F0 is fixed to the specified channel. 1b = F0 may be assigned to any channel.
1	F1 association	0b = F1 is fixed to the specified channel. 1b = F1 may be assigned to any channel.

Bit Position	Field Description	Value Description
...	...	...
15	F15 association	0b = F15 is fixed to the specified channel. 1b = F15 may be assigned to any channel.

### 8.5.62.3 Function Enablement bitmap field

The Function Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical function in the NC. The number of functions shown as enabled in this field shall be equal to the number shown in the Get/Set NC Configuration command. A function may be assigned to a PCIe Endpoint and be enabled and not be assigned to a channel in some implementations (i.e., a non-networking function).

**Table 123 – Function Enablement bitmap field**

Bit Position	Field Description	Value Description
0	F0 status	0b = F0 is not enabled 1b = F0 is enabled
1	F1 status	0b = F1 is not enabled. 1b = F1 is enabled.
...	...	...
31	F31 status	0b = F31 is not enabled. 1b = F31 is enabled

### 8.5.62.4 PCIe Endpoint b Assignment bitmap field

The number of PCIe Endpoint Assignment bitmaps returned in the response is equal to 'b', the number returned in the Get NC Capabilities and Settings Command Enabled PCIe Endpoints field. The PCIe Endpoint b Assignment bitmaps are 32-bit fields in which each bit position corresponds to a physical function in the NC on the specified host bus. If the physical function is assigned to the b<sup>th</sup> Endpoint, even if it not currently enabled, the bit value shall be set to 1b, otherwise the bit is set to 0b.

**Table 124 – PCIe Endpoint b Assignment bitmap field**

Bit Position	Field Description	Value Description
0	F0 status	0b = F0 is not assigned on the specified PCIe Endpoint. 1b = F0 is assigned on the specified PCIe Endpoint.
1	F1 status	0b = F1 is not assigned on the specified PCIe Endpoint. 1b = F1 is assigned on the specified PCIe Endpoint.
...	...	...
31	F15 status	0b = F31 is not assigned on the specified PCIe Endpoint. 1b = F31 is assigned on the specified PCIe Endpoint

### 3007 8.5.62.5 Calculation of Partition ID

3008 When multiple functions are assigned to a channel, they are addressed by a value called the Partition ID.  
 3009 The Partition ID is created by taking the set of Functions that are assigned to a channel and assigning  
 3010 each an index value starting with the lowest numbered Function. A Function assigned to a channel has a  
 3011 Partition ID even if it is not enabled. Partition numbering starts at 0. For example, if F2 and F6 are  
 3012 assigned to channel 3, but only F2 is enabled, then F2 has Partition ID = 0 and F6 has Partition ID = 1 on  
 3013 that channel.

### 3014 8.5.63 Set PF Assignment command ( 0x28 )

3015 The Set PF Assignment command is a Package command that allows the Management controller to  
 3016 enable, disable, and assign PCI Physical Functions (partitions) in the controller to the channels, and, if  
 3017 applicable, to different PCI Endpoints in multi-home or multi-host configurations.

3018 The format of the command payload is dependent on the numbers of Physical Functions, Channels and  
 3019 PCI Endpoints supported by the controller:

- 3020 1) The number of Function Assignments bitmap fields shall be determined by the value (c) of the  
 3021 Channel Count field in the Get Capabilities response.
- 3022 2) The number of Physical Functions allowed to be configured in the Function Assignment and  
 3023 Enablement bitmap fields shall be determined by the value of the Physical Function Count field  
 3024 in the Get NC Capabilities and Settings command response. Assignment in all bitmaps starts at  
 3025 bit 0 and continues sequentially for the number of Functions supported. To support various  
 3026 implementation architectures, the definition of assignment/enablement rules is beyond the  
 3027 scope of this specification.
- 3028 3) If the value (b) of the <PCI Bus Count> field in the <Get Device Capabilities and Settings  
 3029 command> response is greater than 1, the Controller shall also include that number of PCI  
 3030 Endpoint Function Assignment bitmap fields in the command. Controllers that do not support  
 3031 multiple PCI interfaces shall not implement PCI Endpoint Host Function Assignment bitmap  
 3032 fields. PCI Endpoint 0 shall be used if the Controller is configured for single bus operation.

3033 The values configured by this command are held by the controller and only take effect at the next PCI  
 3034 reset. The configuration is persistent unless changed by another Set PF Assignment command or other  
 3035 mechanism.

3036 Table 125 illustrates the packet format of the Set PF Assignment Command.

3037 NOTE: Braces {} denote fields that depend on device capabilities.

3038 **Table 125 – Set PF Assignment Command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Channel 0 Function Assignment bitmap			
	{Channel 1 Function Assignment bitmap}			
	...			
	{Channel c-1 Function Assignment bitmap}			
	Function Enablement bitmap			
	{PCIe Endpoint 0 Function Assignment bitmap}			
	{PCIe Endpoint 1 Function Assignment bitmap}			

Bytes	Bits			
	31..24	23..16	15..08	07..00
	...			
	{PCIe Endpoint <i>b</i> -1 Function Assignment bitmap}			
	Checksum			
	Pad			

### 8.5.63.1 Channel Function Assignment bitmap field

The Channel Function Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical function in the device. If the physical function is assigned to the channel, even if it not currently enabled, the bit value shall be set to 0b1. This allows for a partition ID to be assigned and partition commands to be sent to the function even if it is not enabled.

**Table 126 – Channel Function Assignment bitmap field**

Bit Position	Field Description	Value Description
0	F0 status	0b = F0 is not assigned on the channel. 1b = F0 is assigned on the channel.
1	F1 status	0b = F1 is not assigned on the channel. 1b = F1 is assigned on the channel.
...	...	...
15	F15 status	0b = F15 is not assigned on the channel. 1b = F15 is assigned on the channel

### 8.5.63.2 Function Enablement bitmap field

The Function Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical function in the device.

**Table 127 – Function Enablement bitmap field**

Bit Position	Field Description	Value Description
0	F0 status	0b = F0 is not enabled on the specified channel. 1b = F0 is enabled on the specified channel.
1	F1 status	0b = F1 is not enabled on the specified channel. 1b = F1 is enabled on the specified channel.
...	...	...
15	F15 status	0b = F15 is not enabled on the specified channel. 1b = F15 is enabled on the specified channel

### 8.5.63.3 PCIe Endpoint Assignment bitmap field

The PCIe Endpoint Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical function in the device.

**Table 128 – PCIe Endpoint Assignment bitmap field**

Bit Position	Field Description	Value Description
0	F0 status	0b = F0 is not assigned on the specified PCIe Endpoint. 1b = F0 is assigned on the specified PCIe Endpoint.
1	F1 status	0b = F1 is not assigned on the specified PCIe Endpoint. 1b = F1 is assigned on the specified PCIe Endpoint.
...	...	...
15	F15 status	0b = F15 is not assigned on the specified PCIe Endpoint. 1b = F15 is assigned on the specified PCIe Endpoint

### 8.5.64 Set PF Assignment Response (0xA8)

In the absence of any errors, the channel shall process and respond to the Set PF Assignment Command and send the response packet shown in Table 129.

**Table 129 – Set PF Assignment Response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
24..27	Checksum			
36..39	Pad			

### 8.5.65 Get VF Allocation command (0x35)

The Get VF Allocation command is a Package command that allows the Management controller to receive the current list of PCI Virtual Functions currently being advertised by each Physical Function in PCI Configuration Space.,

See the Set VF Allocation command description for additional information.

Table 130 illustrates the packet format of the Get VF Allocation Command.

**Table 130 – Get VF Allocation Command Packet Format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

**8.5.66 Get VF Allocation Response ( 0xB5 )**

In the absence of any errors, the package shall process and respond to the Get VF Allocation command and send the response packet shown in the table below.

**Table 131 – Get VF Allocation Response packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	<u>Function 0 Alloc</u>	<u>Function 1 Alloc</u>	<u>Function 2 Alloc</u>	<u>Function 3 Alloc</u>
24..27	<u>Function 4 Alloc</u>	...		
	...			
	Checksum			
	Pad			

**8.5.66.1 Function Alloc field**

Field entries contain the number of VFs that each Physical Function is advertising in Configuration Space.

**Table 132 – Function Alloc field**

	Field Description	Value Description
	<u>Function 0 Alloc</u>	Number of VFs currently being advertised by Function 0
	<u>Function 1 Alloc</u>	Number of VFs currently being advertised by Function 1
	...	...
	F	

**8.5.67 Set VF Allocation command ( 0x36 )**

The Set VF Allocation command is a Package command that allows the Management controller to configure the number of PCI Virtual Functions to be advertised in PCI Configuration Space by each of the Physical Functions in the NC. The total number of Virtual Functions the NC supports is returned in the Get NC Capabilities and Settings response and the sum of the VFs configured by this command shall not exceed that total value.

The values configured by this command are held by the controller and only take effect at the next PCI reset. The configuration is persistent unless changed by another Set VF Allocation command or other mechanism.

Table 133 illustrates the packet format of the Set VF Allocation Command.

3081

**Table 133 – Set VF Allocation Command packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Function 0 Alloc	Function 1 Alloc	Function 2 Alloc	Function 3 Alloc
...	Function 4 Alloc	...		
	...			
	Checksum			
	Pad			

3082 **8.5.67.1 Function Alloc field**

3083 Field entries contain the number of VFs that each Physical Function is advertising in Configuration Space

3084

**Table 134 – VF Allocation**

	Field Description	Value Description
	Function 0 Alloc	Number of VFs to be advertised by Function 0
	Function 1 Alloc	Number of VFs to be advertised by Function 1
...	...	...

3085 **8.5.68 Set VF Allocation Response (0xA8)**

3086 In the absence of any errors, the channel shall process and respond to the Set VF Allocation Command  
 3087 and send the response packet shown in Table 135.

3088

**Table 135 – Set PF Assignment Response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
24..27	Checksum			
36..39	Pad			

3089 **8.5.69 Get Channel Configuration command (0x29)**

3090 The Get Channel Configuration command is used to discover the currently configured settings of the  
 3091 channel, including the fabric type, the implemented media type, the number of enabled partitions, if any,  
 3092 and their bandwidth allocation settings where applicable..

3093 Table 136 illustrates the packet format for the Get Channel Configuration command.

3094 **Table 136 – Get Channel Configuration command packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

3095 **8.5.70 Get Channel Configuration response (0xA9)**

3096 In the absence of any errors, the channel shall process and respond to the Get Channel Configuration  
3097 Command and send the response packet shown in Table 137.

3098 Currently no command-specific reason code is identified for this response.

3099 **Table 137 – Get Channel Configuration response packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Fabric Type	Media Type	Max MTU	
24..27	Reserved		Reserved	# Enabled Partitions
28..31	P1 Max TX BW	P1 Min TX BW	P2 Max TX BW	P2 Min TX BW
32..35	Checksum			

3100 **8.5.70.1 Fabric Type field**

3101 The Fabric Type field indicates which personality types are currently enabled on the channel, as  
3102 described in Table 138.

3103 **Table 138 – Fabric Type definitions**

Value	Fabric Type	Value Description
1	Ethernet Mode	Ethernet operation is enabled
2	Fibre Channel Mode	Fibre Channel operation is enabled
3	InfiniBand Mode	InfiniBand operation is enabled
All others	Reserved	Reserved

3104 **8.5.70.2 Max MTU field**

3105 The Max MTU field is used to report the maximum allowed MTU size (Bytes) when the port is configured  
3106 for Ethernet.

### 3107 8.5.70.3 Media Type field

3108 The Media Type field indicates the physical interface type used on the port implementation and if that port  
 3109 supports one or more than one NC-SI channels (for example, some designs may support up to 4  
 3110 independent ports in a QSFP interface), as described in Table 139.

3111 NOTE: An implementation that implements a SFF cage interface into which a RJ-45 transceiver is plugged shall  
 3112 return 'SFF cage' as the media type.

3113 **Table 139 – Media Type bit definitions**

Bit Position	Field Description	Value Description
0	Backplane	0b = The port does not have a backplane interface 1b = The port has a backplane interface
1	Base-T (RJ-45 style)	0b = The port does not have a Base-T interface 1b = The port has a Base-T (RJ-45 style) interface
2	SFF cage	0b = The port does not have an SFF-style interface 1b = The port has an SFF-style interface
3..6	Reserved	Reserved
7	Shared Interface	0b = The port is dedicated to one NC-SI channel 1b = The port is shared between multiple channels

### 3114 8.5.70.4 P(n) Max TX BW Fields

3115 These fields contain the Maximum TX bandwidth allocation of the n<sup>th</sup> enabled partition expressed in % of  
 3116 the physical port link speed.

### 3117 8.5.70.5 P(n) Min TX BW Fields

3118 These fields contain the Minimum TX bandwidth allocation of the n<sup>th</sup> enabled partition expressed in % of  
 3119 the physical port link speed.

### 3120 8.5.71 Set Channel Configuration command (0x2A)

3121 The Set Channel Configuration command allows the Management Controller to configure characteristics  
 3122 of the channel. The TX Bandwidth fields must be set for each enabled partition, but their values may be  
 3123 overridden during operation by other configuration methods (outside of the scope of this specification)'

3124 Table 140 illustrates the packet format of the Set Channel Configuration command.

3125 **Table 140 – Set Channel Configuration command packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Fabric Type	# Partitions	Max MTU	
20..23	P1 Max TX BW	P1 Min TX BW	P2 Max TX BW	P2 Min TX BW
	...			
	Checksum			
	Pad			

### 3126 8.5.71.1 Fabric Type field

3127 The Fabric Type field indicates the personality type to be enabled on the channel, as described in Table  
 3128 141. The contents of this field may be ignored if the channel only supports one fabric type. The Fabric  
 3129 type is a channel property shared by all partitions assigned to the channel.

3130 **Table 141 – Fabric Type definitions**

Value	Fabric Type	Value Description
1	Ethernet Mode	Enable Ethernet operation
2	Fibre Channel Mode	Enable Fibre Channel operation
3	InfiniBand Mode	Enable InfiniBand operation
all others	Reserved	Reserved

### 3131 8.5.71.2 Max MTU field

3132 The Max MTU field is used to configure the maximum allowed MTU size (Bytes) when the port is  
 3133 configured for Ethernet.

### 3134 8.5.71.3 # Partitions

3135 The Number of Partitions field indicates the number of Functions that have been assigned to the  
 3136 channel/port in the Set PF Assignment command. This field is used only to provide the number of  
 3137 partitions present in the bandwidth fields and does not have the ability to change the number of assigned  
 3138 partitions on the channel. Each assigned partition must be allocated min and max TX bandwidth values  
 3139 when enabled.

3140 The initial value is generally expected to be one partition enabled per port and if modified, the new value  
 3141 should persist across system boot and power cycles.

### 3142 8.5.71.4 P(n) Max TX BW fields

3143 These fields contain the Maximum TX bandwidth allocation of the n<sup>th</sup> enabled partition expressed in % of  
 3144 the physical port link speed. Oversubscription of partition maximum bandwidth is allowed. The field value  
 3145 is an integer ranging from 0 to 100<sub>10</sub>.

3146 The initial value is generally expected to be 100% per partition, allowing each enabled partition full use of  
 3147 the channel bandwidth if no other partition has traffic. If modified, the new value should persist across  
 3148 system boot and power cycles.

### 3149 8.5.71.5 P(n) Min TX BW field

3150 These fields contain the Minimum TX bandwidth allocation of the  $n^{\text{th}}$  enabled partition expressed in % of  
 3151 the physical port link speed. This is interpreted as committed bandwidth to the partition and as such the  
 3152 Min TX BW fields of all enabled partitions on the port must sum to 100%. The field value is an integer  
 3153 ranging from 0 to 100<sub>10</sub>.

3154 The initial value is generally expected to be equal weighting among all enabled partitions, allowing each  
 3155 enabled partition equal use of the channel bandwidth. If modified, the new value should persist across  
 3156 system boot and power cycles

### 3157 8.5.72 Set Channel Configuration response (0xAA)

3158 The package shall, in the absence of a checksum error or identifier mismatch, always accept the Set  
 3159 Channel Configuration command and send a response (see Table 142).

3160 **Table 142 – Set Channel Configuration response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

### 3161 8.5.73 Get Partition Configuration command (0x2B)

3162 The Get Partition Configuration command is used to discover additional optional functions supported by  
 3163 the channel, such as the number of unicast/multicast addresses supported, the amount of buffering in  
 3164 bytes available for packets bound for the Management Controller, and so on.

3165 Table 143 illustrates the packet format for the Get Partition Configuration command.

3166 **Table 143 – Get Partition Configuration command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Partition ID	Reserved		
20..23	Checksum			
24..45	Pad			

#### 3167 8.5.73.1 Partition ID field

3168 The Partition ID field is the identifier for the function on the channel as defined in clause 8.5.63

### 3169 8.5.74 Get Partition Configuration response (0xAB)

3170 In the absence of any errors, the channel shall process and respond to the Get Partition Configuration  
 3171 Command and send the response packet shown in Table 144.

3172 Currently no command-specific reason code is identified for this response.

3173 **Table 144 – Get Partition Configuration response packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Personality Cfg	Personality Spt	Configuration Flags	
24..27	Max TX BW	Min TX BW	Advertised VF Count	
28..31	PCI DID		PCI VID	
32..35	PCI SSID		PCI SVID	
36..39	PCI Endpoint #	PCI Bus #	PCI Device #	PCI Function #
40..43	Reserved	Address Count	Address TLVs	
44..47	Address (MSB)	Address	...	...
	...	...	...	...
	Checksum			

#### 3174 8.5.74.1 Personality Cfg field

3175 The Personality Configured field indicates which personality type(s) are currently enabled on the partition,  
3176 as described in Table 145.

3177 NOTE: Some implementations may support multiple personalities being simultaneously enabled.

3178 **Table 145 – Personality Cfg bit definitions**

Bit Position	Field Description	Value Description
0	Ethernet Status	0b = Ethernet operation is not enabled 1b = Ethernet operation is enabled
1	Fibre Channel Status	0b = Fibre Channel operation is not enabled 1b = Fibre Channel operation is enabled
2	Fibre Channel over Ethernet Status	0b = Fibre Channel over Ethernet operation is not enabled 1b = Fibre Channel over Ethernet operation is enabled
3	InfiniBand Status	0b = InfiniBand operation is not enabled 1b = InfiniBand operation is enabled
4	iSCSI Offload Status	0b = iSCSI Offload operation is not enabled 1b = iSCSI Offload operation is enabled
5	RDMA Status	0b = RDMA operation is not enabled 1b = RDMA operation is enabled
6	NVMe	0b = NVMe operation is not enabled 1b = NVMe operation is enabled
7	Reserved	Reserved

3179 **8.5.74.2 Personality Spt field**

3180 The Personality Supported field indicates which personality types the partition supports, as described in  
 3181 Table 146.

3182 **Table 146 – Personality Spt bit definitions**

Bit Position	Field Description	Value Description
0	Ethernet Support	0b = Ethernet operation is not supported 1b = Ethernet operation is supported
1	Fibre Channel Support	0b = Fibre Channel operation is not supported 1b = Fibre Channel operation is supported
2	Fibre Channel over Ethernet Support	0b = Fibre Channel over Ethernet operation isn't supported 1b = Fibre Channel over Ethernet operation is supported
3	InfiniBand Support	0b = InfiniBand operation is not supported 1b = InfiniBand operation is supported
4	iSCSI Offload Support	0b = iSCSI Offload operation is not supported 1b = iSCSI Offload operation is supported
5	RDMA Support	0b = RDMA operation is not supported 1b = RDMA operation is supported
6	NVMe	0b = NVMe Offload operation is not supported 1b = NVMe Offload operation is supported
7	Reserved	Reserved

3183 **8.5.74.3 Configuration Flags field**

3184 The Configuration Flags field indicates which optional features of this specification the channel supports,  
 3185 as described in Table 147.

3186 **Table 147 – Configuration Flags bit definitions**

Bit Position	Field Description	Value Description
0	Host Driver Status	0b = When reporting is supported, Host driver is not present 1b = When reporting is supported, Host driver is present
1	Host Driver Status Reporting	0b = Host Driver status reporting is not supported. 1b = Host Driver status reporting (bit 0) is supported.
2..3	Partition Link Status	00b = When reporting is supported, Partition Link is down 01b = When reporting is supported, Partition Link is forced up 01b = When reporting is supported, Partition Link follows Channel Link 11b = Reserved
4	Partition Link Status Reporting	0b = Partition Link Status reporting is not supported. 1b = Partition Link Status reporting (bit 2) is supported.

Bit Position	Field Description	Value Description
5	Boot Status	0b = The partition is not configured for boot. 1b = The partition is configured for boot.
6	Bootable	0b = The partition supports boot and reporting 1b = The partition does not support boot
7..31	Reserved	Reserved

#### 3187 8.5.74.4 Partition Link fields

3188 This fields describe the ability of a partition to support traffic when the partition is assigned to a PCI bus  
3189 and NC-SI channel and either its associated physical port link is up or the implementation supports  
3190 internal communication between partitions when the physical port link is down.

#### 3191 8.5.74.5 Max TX BW field

3192 This field contains the Maximum TX bandwidth allocation of the partition expressed in % of the physical  
3193 port link speed. The % value ranges from 0 to 100<sub>10</sub> represented as an integer.

#### 3194 8.5.74.6 Min TX BW field

3195 This field contains the Minimum TX bandwidth allocation of the partition expressed in % of the physical  
3196 port link speed. This is interpreted as committed bandwidth to the partition and as such the Min TX BW  
3197 fields of all enabled partitions on the port must sum to 100%. The % value ranges from 0 to 100<sub>10</sub>  
3198 represented as an integer.

#### 3199 8.5.74.7 Advertised VF Count field

3200 The Advertised VF Count field indicates the number of Virtual Functions being advertised in PCI  
3201 Configuration Space by the partition's PF.

#### 3202 8.5.74.8 PCI DID

3203 The current PCI Device ID of the Partition

#### 3204 8.5.74.9 PCI VID

3205 The current PCI Vendor ID of the Partition

#### 3206 8.5.74.10 PCI SSID

3207 The current PCI Subsystem ID of the Partition

#### 3208 8.5.74.11 PCI SVID

3209 The current PCI Subvendor ID of the Partition

#### 3210 8.5.74.12 PCIe Endpoint #

3211 The identifier indicating which PCIe Endpoint on the NC the partition is associated with

3212 **8.5.74.13 PCI Bus #**

3213 The assigned primary PCI Bus number assigned to the partition in the host system's bus enumeration  
3214 process

3215 **8.5.74.14 PCI Device #**

3216 The assigned PCI Device number assigned to the partition except in the cases of ARI mode operation  
3217 when it shall contain the arbitrary value of 0xFF

3218 **8.5.74.15 PCI Function #**

3219 The assigned PCI Function number assigned to the partition in the host system's bus enumeration  
3220 process

3221 **8.5.74.16 Address Count field**

3222 This field indicates the number of permanent and virtual addresses reported by the partition.

3223 **8.5.74.17 Address TLVs**

3224 These TLVs show the permanently programmed and current addresses being used by the partition.

3225 **Table 148 – Address Type-Length Field Bit Definitions**

Bit Position	Field Description	Value Description
7..0	Address Type	<p>The following type encodings shall be used to indicate the address values that are permanently assigned to the partition. The response shall include all types whether or not that mode of operation is active, or the partition is enabled:</p> <p>0x0 = Reserved</p> <p>0x1 = Ethernet MAC</p> <p>0x2 = iSCSI Offload (Ethernet MAC)</p> <p>0x3 = Fibre Channel World Wide Node Name</p> <p>0x4 = Fibre Channel World Wide Port Name</p> <p>0x5 = FCoE-FIP MAC</p> <p>0x6 = InfiniBand Node GUID</p> <p>0x7 = InfiniBand Port GUID</p> <p>0x8 = InfiniBand VPort/LID</p> <p>The following type encodings shall be used to indicate all address values that are currently in use by the partition based on configured mode of operation. These may be the permanent address or a programmatically assigned address.</p> <p>:</p> <p>0xF1 = Ethernet MAC</p> <p>0xF2 = iSCSI Offload (Ethernet MAC)</p> <p>0xF3 = Fibre Channel World Wide Node Name</p>

Bit Position	Field Description	Value Description
		0xF4 = Fibre Channel World Wide Port Name 0xF5 = FCoE-FIP MAC 0xF6 = InfiniBand Node GUID 0xF7 = InfiniBand Port GUID 0xF8 = InfiniBand VPort/LID  all others = Reserved
15..8	Address Length	The length indicates the number of bytes used in the address

### 3226 8.5.75 Set Partition Configuration command (0x2C)

3227 The Set Partition Configuration command allows the Management Controller to configure various settings  
 3228 of the partition including virtual addresses, VF allocation and other parameters.

3229 The Set Partition Configuration command is addressed to the channel with the Partition ID field set to the  
 3230 index/ordinal of the target PF on the channel.

3231 The partition's personality configuration and VF count settings may be made persistent if written to the  
 3232 NVRAM via the Commit command. These settings take effect at the next PCI Reset.

3233 Table 149 illustrates the packet format of the Set Partition Configuration command.

3234 **Table 149 – Set Partition Configuration command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Partition ID	Personality Cfg	VF Count	
20..23	Partition Link Control	Reserved	Address Count	Address TLV
24..27	Checksum			
28..45	Pad			

### 3235 8.5.75.1 Personality Cfg field

3236 The Personality Configuration field indicates which personality type(s) shall be enabled on the partition,  
 3237 as described in Table 150. Any attempt to enable a personality not shown as supported in clause 8.5.74.2  
 3238 shall be cause the command to fail with Parameter Is Invalid reason code. In some implementations it  
 3239 may be appropriate to select more than one personality at a time, for instance Ethernet and RDMA.  
 3240

3241

**Table 150 – Personality Cfg bit definitions**

Bit Position	Field Description	Value Description
0	Ethernet Status	0b = Disable Ethernet operation 1b = Enable Ethernet operation
1	Fibre Channel Status	0b = Disable Fibre Channel operation 1b = Enable Fibre Channel operation
2	Fibre Channel over Ethernet Status	0b = Disable Fibre Channel over Ethernet operation 1b = Enable Fibre Channel over Ethernet operation
3	InfiniBand Status	0b = Disable InfiniBand operation 1b = Enable InfiniBand operation
4	iSCSI Offload Status	0b = Disable iSCSI Offload operation 1b = Enable iSCSI Offload operation
5	RDMA Status	0b = Disable RDMA operation 1b = Enable RDMA operation
6	NVMe	0b = Disable NVMe operation 1b = Enable NVMe operation
7	Reserved	Reserved

3242 **8.5.75.2 VF Count**

3243 The VF Count field contains the number of VFs to be advertised in PCI Configuration Space by the  
3244 partition.

3245 **8.5.75.3 Partition Link Control**

3246 Table 151 describes the values for the Partition Link Control field.

3247 **Table 151 – Values for the Partition Link Control field (8-bit field)**

Value	Description
0x0	Partition Link is down
0x1	Partition Link is forced up
0x2	Partition Link follows Channel link state
0x3..0xFF	Reserved

3248 **8.5.75.4 Address Count field**

3249 The Address Count field contains the number of partition virtual addresses to be configured as specified  
3250 in the Address TLV field.

3251 **8.5.75.5 Address TLV**3252 **Table 152 – Address Type-Length field bit definitions**

Bit Position	Field Description	Value Description
7..0	Address Type	<p>Addresses specified herein override the permanent or factory-programmed network address to be used by the partition based on configured mode of operation. To return to using the permanent address, supply either an address of 0 or the permanent address in this field or remove power from the NC.</p> <p>:</p> <p>0xF1 = Ethernet MAC</p> <p>0xF2 = iSCSI Offload (Ethernet MAC)</p> <p>0xF3 = Fibre Channel World Wide Node Name</p> <p>0xF4 = Fibre Channel World Wide Port Name</p> <p>0xF5 = FCoE-FIP MAC</p> <p>0xF6 = InfiniBand Node GUID</p> <p>0xF7 = InfiniBand Port GUID</p> <p>0xF8 = InfiniBand VPort/LID</p> <p>All others = Reserved</p>
15..8	Address Length	The length indicates the number of bytes used in the address

3253 **8.5.76 Set Partition Configuration response ( 0xAC )**

3254 The package shall, in the absence of a checksum error or identifier mismatch, always accept the Set  
 3255 Partition Configuration command and send a response (see Table 153).

3256 **Table 153 – Set Partition Configuration response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

3257 **8.5.77 Get Boot Config Command (0x2D)**

3258 The Get Boot Config Command allows the Management Controller to query for the Boot Initiator settings  
 3259 of a given Boot Protocol type configured on the channel/PF/partition and stored in the NVRAM of the  
 3260 controller.

3261 If the command is sent to a destination that exists but that does not support the specified Boot Protocol  
 3262 type, the command execution shall fail with a reason code indicating a Parameter Is Invalid, Unsupported,  
 3263 or Out-of-Range.

3264 Table 154 illustrates the packet format of the Get Boot Config command.

3265 **Table 154 – Get Boot Config command packet**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Partition ID	Reserved	Reserved	Protocol Type
20..23	Checksum			
24..45	Pad			

### 3266 8.5.77.1 Protocol Type field

3267 The Protocol Type field specifies the boot protocol for which configuration data is requested.

3268 **Table 155 – Protocol Type field**

Bit Position	Field Description	Value Description
7..0	Boot Protocol Type	0x0 = PXE (legacy) 0x1 = iSCSI Offload 0x2 = FCoE Offload 0x3 = FC 0x4 = NVMe (independent of fabric type) 0x5–0xFF = Reserved

3269 NOTE: Selection of protocol type NVMe covers NVMeoF, NVMe over RDMA, NVMeoFC, and NVMeoIB depending  
 3270 on the configured fabric type of the channel.

### 3271 8.5.78 Get Boot Config Response (0xAD)

3272 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get Boot  
 3273 Config command and send a response.

3274 The Get Boot Config Response frame contains the currently stored settings for the specified Boot  
 3275 Protocol type contained in the controller's NVRAM that the channel/PF/partition will use in a boot  
 3276 operation done locally by the adapter. Settings that the Controller supports but does not have a value for  
 3277 (e.g., have no initial or current value) should be included in the Response and have a length of 0.

3278 All attribute values returned by this command shall be in unterminated ASCII string format.

3279 Table 156 illustrates the packet format of the Get Boot Config Response.

3280

**Table 156 – Get Boot Config Response packet**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Reserved		Protocol Type	Number of TLVs
24..	Type-Length Field #1		Value Field #1	
...	Type-Length Field #2		Value Field #2	
...	...			
....	Checksum			

3281 **8.5.78.1 Protocol Type field**

3282 The Protocol Type field specifies the boot protocol for which boot attributes are being returned.

3283 **Table 157 – Protocol Type field**

Bit Position	Field Description	Value Description
7..0	Boot Protocol Type	0x0 = PXE 0x1 = iSCSI 0x2 = FCoE 0x3 = FC 0x4 = NVMe (independent of fabric type) 0x5-0xFF = Reserved

3284 NOTE: Selection of protocol type NVMe covers NVMeoF, NVMe over RDMA, NVMeoFC, and NVMeoIB depending  
 3285 on the configured fabric type of the channel.

3286 **8.5.78.2 Boot Protocol Type-Length-Value fields**

3287 The set of boot attributes (one of the following 4 tables) that correspond to the specified Protocol Type in  
 3288 the Command are returned as TLVs in the Response.

3289 **Table 158 – PXE Boot Protocol Type-Length field**

### 3297 8.5.79 Set Boot Config command (0x2E)

3298 The Set Boot Config command allows the Management Controller to send to the channel/PF/partition the  
 3299 Boot settings to be used by the channel/PF/partition in conducting boot operations of the specified type.

3300 The Network Controller shall apply the attribute values in the order received in this command (e.g., TLV1  
 3301 before TLV2, etc.) so that any dependency relationships are maintained.

- 3302 See the Get Boot Config Command for the definition of the **command** fields.
- 3303 All string values specified in this command shall be in unterminated ASCII string format.
- 3304 A NC that does not support or is not in partitioning mode shall have the Partition ID field programmed as  
3305 0x00.
- 3306 A TLV length value of 0 indicates the clearing of the current value of the attribute to null or no value.
- 3307 A maximum of 32 TLVs may be sent in any one instance of the Set Boot Config command.
- 3308 If the command is sent to a destination that exists but that does not support the specified Boot Protocol  
3309 type, the command execution shall fail with a reason code of Parameter Is Invalid, Unsupported, or Out-  
3310 of-Range.

3311 **Table 163 – Set Boot Config command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Partition ID		Protocol Type	Number of TLVs
24..	Type-Length Field #1.		Value Field #1.	
....	Type-Length Field #2		Value Field #2	
....	....			
....	Checksum (3..2)		Checksum (1..0)	
....	Pad			

### 3312 8.5.80 Set Boot Config Response (0xAE)

- 3313 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Set Boot  
3314 Config command and send a response.
- 3315 Only if all the TLVs are accepted without error then the Command Completed/No Error response/reason  
3316 code shall be returned with the TLV Error Reporting field set to all 0's.
- 3317 If the command is sent to a destination that exists but that does not support the specified Boot Protocol  
3318 type, the command response shall return the Parameter Is Invalid, Unsupported, or Out-of-Range reason  
3319 code.
- 3320 If there are errors in any of the TLVs included in the Set command, the entire command is deemed to fail,  
3321 and no configuration changes are to be made by the controller. The TLV Error Reporting field shall be  
3322 used to provide individual status reporting on the TLVs received.

3323

**Table 164 – Set Boot Config Response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	TLV Error Reporting			
28..31	Checksum			
32..45	Pad			

3324

**8.5.80.1 TLV Error Reporting field**

3325

The TLV Error Reporting field is a bitmap indicating which TLVs in the incoming Set command were processed without error, and which were not. The bit order corresponds to the order of TLVs in the incoming Set command as shown. There is a 1:1 correspondence between incoming TLVs and the active bits in this field. If fewer than 32 TLVs are transmitted, the bits corresponding to the unsent TLVs shall be set to 0.

3326

3327

3328

3329

3330

**Table 165 – TLV Error Reporting field**

Bit Position	Field Description	Value Description
0	TLV #1 status	0b = 0 No error detected in TLV1 0b = 1 Error detected in TLV1
n	TLV n+1 status	1b = 0 No error detected in TLV n+1 or TLV n+1 not present 1b = 1 Error detected in TLV n+1  all others = Reserved

3331

**8.5.81 Get Partition Statistics command ( 0x2F )**

3332

The Get Partition Statistics command is used to retrieve network statistics relevant to the partition from the NC. For example, the MC should only request Ethernet statistics from a partition configured for Ethernet operation. The defined responses are customized for each personality type.

3333

3334

3335

Implementation of this command is conditional and is required only for NCs that support partitioning. Implementation of each response type is conditional based on the NC supporting the specified type of operation on the partition.

3336

3337

3338

The NC shall return in the response a value of 0xFFFFFFFF for unsupported 32-bit counters and 0xFFFFFFFFFFFFFFFF for unsupported 64-bit counters. For implementations that declare a particular counter only occupies 32 bits in a defined 64-bit (upper/lower) field, the lower field shall be used to provide the count and the upper field shall be set to 0xFFFFFFFF.

3339

3340

3341

3342

As the intent of the command is to retrieve live statistics from enabled partitions, if the command is sent to a Partition ID that doesn't exist in the current configuration or if the Stats type does not match the configured personality of the partition, the command shall fail with the Parameter is Invalid reason code.

3343

3344

3345 **Table 166 – Get Partition Statistics command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00

### 3354 8.5.82.1 Counter Sizes field

3355 The NC shall indicate in the Counter Sizes field whether the implementation uses 32-bit counters or 64-bit  
 3356 counters in those counter fields above that are defined as 64-bit.

3357 **Table 169 – Counter Sizes field format**

Bit Position	Field Description	Value Description
0	Total Bytes Received	0b = 32-bit 1b = 64-bit
1	Total Bytes Transmitted	0b = 32-bit 1b = 64-bit
2	Total Unicast Bytes Received	0b = 32-bit 1b = 64-bit
3	Total Multicast Bytes Received	0b = 32-bit 1b = 64-bit
4	Total Broadcast Bytes Received	0b = 32-bit 1b = 64-bit
5	Total Unicast Bytes Transmitted	0b = 32-bit 1b = 64-bit
6	Total Multicast Bytes Transmitted	0b = 32-bit 1b = 64-bit

Bit Position	Field Description	Value Description
7	Total Broadcast Bytes Transmitted	0b = 32-bit 1b = 64-bit

### 3358 8.5.82.2 Counters Cleared from Last Read field

3359 The NC shall indicate in the Counters Cleared from Last Read field whether the corresponding fields have  
3360 been cleared since they were last read over NC-SI.

3361 **Table 170 – Counters Cleared from Last Read field format**

Bit Position	Field Description	Value Description
0	Total Bytes Received	0b = Not Cleared 1b = Cleared
1	Total Bytes Transmitted	0b = Not Cleared 1b = Cleared
2	Total Unicast Packets Received	0b = Not Cleared 1b = Cleared
3	Total Multicast Packets Received	0b = Not Cleared 1b = Cleared
4	Total Broadcast Packets Received	0b = Not Cleared 1b = Cleared
5	Total Unicast Packets Transmitted	0b = Not Cleared 1b = Cleared
6	Total Multicast Packets Transmitted	0b = Not Cleared 1b = Cleared
7	Total Broadcast Packets Transmitted	0b = Not Cleared 1b = Cleared
8	Total Unicast Bytes Received	0b = Not Cleared 1b = Cleared
9	Total Multicast Bytes Received	0b = Not Cleared 1b = Cleared

11	Total Unicast Bytes Transmitted	0b = Not Cleared 1b = Cleared
12	Total Multicast Bytes Transmitted	0b = Not Cleared 1b = Cleared
13	Total Broadcast Bytes Transmitted	0b = Not Cleared 1b = Cleared
15..14	Reserved	

### 3362 8.5.83 Get Partition Statistics response for FCoE ( 0xAF )

3363 In the absence of any errors, the channel shall process and respond to the Get Partition Statistics  
3364 Command and send the response packet shown below when the Stats Type indicates FCoE.

3365 Currently no command-specific reason code is identified for this response.

3366 **Table 171 – Get Partition Statistics (FCoE) response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header

6	Total Write Packets Transmitted	0b = 32-bit 1b = 64-bit
7	Reserved	

### 3410 8.5.86.2 Counters Cleared from Last Read

3411 The NC shall indicate in the Counters Cleared from Last Read field whether the corresponding fields have  
 3412 been cleared since they were last read over NC-SI.

3413 **Table 182 – Counters Cleared from Last Read field format**

Bit Position	Field Description	Value Description
0	Total RDMA Bytes Received	0b = Not Cleared 1b = Cleared
1	Total RDMA Bytes Transmitted	0b = Not Cleared 1b = Cleared
2	Total RDMA Packets Received	0b = Not Cleared 1b = Cleared
3	Total RDMA Packets Transmitted	0b = Not Cleared 1b = Cleared
4	Total Read Request Packets Transmitted	0b = Not Cleared 1b = Cleared
5	Total Send Packets Transmitted	0b = Not Cleared 1b = Cleared
6	Total Write Packets Transmitted	0b = Not Cleared 1b = Cleared
15..7	Reserved	

### 3414 8.5.87 Get Partition Statistics Response for Fibre Channel (0xAF)

3415 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get  
 3416 Partition Statistics command and send a response when the Stats Type indicates FC.

3417 Table 183 illustrates the packet format of the Get FC Statistics Response.

3418 **Table 183 – Get Partition Statistics (FC) Response packet**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Stats Type	Reserved	Counters Cleared from Last Read	
24..27	Total FC Frames Received			

Bytes	Bits			
	31..24	23..16	15..08	07..00
28..31	Total FC Frames Transmitted			
32..35	Receive KB Count			
36..39	Transmit KB Count			
40..43	FC Sequences Received			
44..47	FC Sequences Transmitted			
48..51	Link Failures			
52..55	Loss of Signal			
56..59	Invalid CRCs			
60..63	Checksum (3..2)		Checksum (1..0)	

### 3419 8.5.87.1 Counters Cleared from Last Read field

3420 The FC Controller shall also indicate in the Counters Cleared from Last Read field whether the  
 3421 corresponding fields has been cleared since it was last read via NC-SI. The Counters Cleared from Last  
 3422 Read fields should have the format shown in Table 184.

3423 **Table 184 – Counters Cleared from Last Read field format**

Bit Position	Field Description	Value Description
0	Total FC Frames Received	0b = Not Cleared 1b = Cleared
1	Total FC Frames Transmitted	0b = Not Cleared 1b = Cleared
2	Receive KB Count	0b = Not Cleared 1b = Cleared
3	Transmit KB Count	0b = Not Cleared 1b = Cleared
4	FC Sequences Received	0b = Not Cleared 1b = Cleared
5	FC Sequences Transmitted	0b = Not Cleared 1b = Cleared
6	Link Failures	0b = Not Cleared 1b = Cleared
7	Loss of Signal	0b = Not Cleared 1b = Cleared
8	Invalid CRCs	0b = Not Cleared 1b = Cleared
15..9	Reserved	

### 8.5.87.2 FC Statistics Counter definitions

**Table 185 – FC Statistics**

Name	Meaning
Total FC Frames Received	Counts the number of FC frames received by the port
Total FC Frames Transmitted	Counts the number of FC frames transmitted by the port
Receive KB Count	Counts the number of kilobytes transmitted by the port
Transmit KB Count	Counts the number of kilobytes transmitted by the port
FC Sequences Received	Counts the number of FC sequences received by the port
FC Sequences Transmitted	Counts the number of FC sequences transmitted by the port
Link Failures	Counts the number of times the link has failed.
Loss of Signal	Counts the number of times the signal was lost.
Invalid CRCs	Counts the number of CRC errors detected.

### 8.5.88 Get FC Link Status command (0x31)

The Get FC Link Status command allows the Management Controller to query the channel for potential link status and error conditions (see Table 186).

Implementation of this command is conditional and is required only for controllers supporting native Fibre Channel.

Implementation Note:

Some controllers may include a port trunking (bonding) capability in which one (or more) channels will map to multiple physical ports. FC trunking (bonding) is based on the following rules:

- FC controllers provide a maximum of 4 physical ports
- All ports are configured to the same speed
- If trunking is enabled, all ports become involved in a bond, no standalone ports remain
- Ports may bond in pairs or all together
- Dual port controllers bond Ports 1&2 and present one channel to the MC
- Quad port controllers bond Ports (1&2) [trunk 1] and {3&4} [trunk2] or {1&2&3&4} and present two or one channel(s) respectively

3442

**Table 186 – Get FC Link Status command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Reserved	Reserved	Reserved	Reserved
20..23	Checksum (3..2)		Checksum (1..0)	
24..27	Pad			

3443 **8.5.89 Get FC Link Status Response ( 0xB1 )**

3444 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get FC  
 3445 Link Status command and send a response (see Table 187).

3446

**Table 187 – Get FC Link Status Response packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	# of FC Ports	FC Trunk Status	FC Link Status	Trunk Speeds
24..27	Channel 1 Link Speed	Channel 2 Link Speed	Channel 3 Link Speed	Channel 4 Link Speed
28..31	Checksum			
33..36	Pad			

3447 **8.5.89.1 # of FC Ports field**

3448 This is an integer value that specifies the total number of physical ports on the Package

3449 **8.5.89.2 FC Trunk Status field**

3450 This field indicates if the physical port is a member of a FC trunk.

3451

**Table 188 – FC Trunk Status field bit definitions**

Bit Position	Field Description	Value Description
0	Port 1 Trunk Flag	0b = Physical Port 1 Is not a member of a trunk 1b = Physical Port 1 Is a member of a trunk
1	Port 2 Trunk Flag	0b = Physical Port 2 Is not a member of a trunk 1b = Physical Port 2 Is a member of a trunk
2	Port 3 Trunk Flag	0b = Physical Port 3 Is not a member of a trunk 1b = Physical Port 3 Is a member of a trunk
3	Port 4 Trunk Flag	0b = Physical Port 4 Is not a member of a trunk 1b = Physical Port 4 Is a member of a trunk

Bit Position	Field Description	Value Description
7..4	Reserved	None

### 3452 8.5.89.3 FC Link Status field

3453 Table 189 describes the FC Link Status field bit definitions.

3454 **Table 189 – FC Link Status field bit definitions**

Bit Position	Field Description	Value Description
0	Port 1 Link Flag	0b = Physical Port 1 Link is down 1b = Physical Port 1 Link is up
1	Port 2 Link Flag	0b = Physical Port 2 Link is down 1b = Physical Port 2 Link is up
2	Port 3 Link Flag	0b = Physical Port 3 Link is down 1b = Physical Port 3 Link is up
3	Port 4 Link Flag	0b = Physical Port 4 Link is down 1b = Physical Port 4 Link is up
7..5	Reserved	None

### 3455 8.5.89.4 Trunk Speeds field

3456 The percentage of the configured trunk speed that is currently available represented as an integer.

3457 Table 190 describes the Trunk Speeds field.

3458 **Table 190 – Trunk Speeds field**

Bit Position	Field Description	Value Description
3..0	Trunk 1 Percentage Speed	Percentage of the Trunk 1 configured link speed that is available expressed as hex value. Not applicable if no Trunks are configured.  0x0 = 0% 0x1 = 25% 0x2 = 50% 0x3 = 75% 0x4 = 100%
7..4	Trunk 2 Percentage Speed	Percentage of the Trunk 2 configured link speed that is available (expressed as hex value. Not applicable if two Trunks are not configured.-  0x0 = 0% 0x2 = 50% 0x4 = 100%

**8.5.89.5 FC Link Speed field**

The Link Speed field provides a link speed based on NC-SI Channel configuration. If the number of FC ports is equal to the number of reported NC-SI channels, then trunking is not active, and the reported speed is the speed of the channel on the port. In two- or four-port trunking modes, the number of FC ports will be twice or four times the number of reported NC-SI channels and the reported configured link speed is the sum of the individual link speeds in the trunk. If one or more of the member links goes down the reported link speed will not change, but the FC Link Status and Trunk Speed fields will provide the indication that the trunk is not operating at its stated speed.

Table 191 describes the FC Link Speed field bit definitions.

**Table 191 – FC Link Speed field**

Value	Field Description	Value Description
0	Link Speed	0x0 = No link speed established 0x1 = FC2 0x2 = FC4 0x3 = FC8 0x4 = FC16 0x5 = FC32 0x6 = FC64 0x7 = FC128 0x8 = FC256
Others	Reserved	None

**8.5.90 Get Transceiver Management Data command (0x32)**

The Get Transceiver Management Data command is used to retrieve 128-byte blocks of management and inventory data stored in the passive copper cable or optical transceiver module associated with the channel. Different standards and specifications exist (e.g., +SFF and [CMIS](#)) in the industry for this management data, but they share common data access methods allowing this command to successfully operate with the known variety of module interface specifications.

A two-byte Type identifier is used to specify the bank and page index of the target data to be returned. The older SFF-type specifications do not use the term 'bank', instead they use upper and lower page terminology. For this command the lower page is considered Bank 0 and the upper page Bank 1. Some devices only support 1 bank and therefore will only respond with data with the bank index set to 0x00.

The lower 128 bytes of page 00h typically contains more important time-critical data. The upper 128 bytes of page 00h contains static inventory information. The implementation may read and cache the

3481 upper 128 bytes once upon power on or module insertion to expedite processing of requests for page  
3482 00h data.

3483 For a given module, the NC shall support reading of all mandatory pages defined by the transceiver's  
3484 Management Data specification. The reading of optional and Vendor-defined pages and any writing of  
3485 pages is implementation dependent.

3486 This command shall fail as unsupported on backplane and RJ-45 implementations.

3487 Table 143 illustrates the packet format for the Get Transceiver Management Data command.

3488 **Table 192 – Get Transceiver Management Data command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Requested Bank	Requested Page	Reserved	Flags
20..23	Checksum			
24..45	Pad			

#### 3489 **8.5.90.1 Requested Bank field**

3490 The Requested Bank field is the value of the bank data being requested.

#### 3491 **8.5.90.2 Requested Page field**

3492 The Requested Page field is the value of the page data being requested.

#### 3493 **8.5.90.3 Flags field**

3494 **Table 193 – Flag field bit definitions**

Bit Position	Field Description	Value Description
0	Page Upper Flag	0b = Requesting lower page data 1b = Requesting upper page data
7..1	Reserved	None

#### 3495 **8.5.91 Get Transceiver Management Data response ( 0xB2 )**

3496 In the absence of any errors, the NC shall process and respond to the Get Transceiver Management Data  
3497 Command and send the response packet shown in Table 144.

3498 Currently no command-specific reason code is identified for this response.

3499 If there is no module installed or module is not present, then the NC shall return response/reason codes  
3500 Command Unavailable/Information not available.

3501 The NC shall return the Command Failed response code with the following reason codes for different  
3502 conditions:

3503 If the Requested Bank or Page number does not exist, then the NC shall return reason code Parameter  
3504 Out-of-Range.

3505 If the module is resetting or powering up, then the NC shall return reason code Information Not Available.

3506 If the module is powered down, then the NC shall return reason code Secondary Device Not Powered.

3507 If the module cannot respond with data in the allocated time, then the NC shall either return Command  
3508 Timeout or Delayed Response as supported by the implementation.

3509 **Table 194 – Get Transceiver Management Data response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Max Bank	Max Page	Bank Number	Page Number
24..27	Data <sub>0</sub>	Data <sub>1</sub>	...	
48..51	Checksum			

#### 3510 8.5.91.1 Max Bank field

3511 The Max Bank field contains the value of the highest Bank number supported by the module. If the  
3512 module type does not support Banks, the field shall be set to 0x00.

#### 3513 8.5.91.2 Max Page field

3514 The Max Page field contains the value of the highest Page number in the current Bank supported by the  
3515 module. If the NC has not or cannot determine the highest Page number, then the value of 0xFF shall be  
3516 returned.

#### 3517 8.5.91.3 Bank Number field

3518 The Bank Number field contains the value of the Bank number requested by the command.

#### 3519 8.5.91.4 Page Number field

3520 The Page Number field contains the value of the Page number requested by the command.

#### 3521 8.5.91.5 Module Type Decode

3522 [SFF-8024](#) provides a mapping of module types, their identifiers reported in \_\_\_\_ and the Management  
3523 Interface Specification they comply with.

3524 **Table 195 – Module Type definitions**

Identifier	Form Factor	Management Interface Specification
0x02	Module soldered to PCB	<a href="#">SFF-8472</a>
0x03	SFP+ / SFP28 and later	<a href="#">SFF-8472</a>
0x0D	QSFP+	<a href="#">SFF-8436</a>

### 3525 8.5.92 Get InfiniBand Link Status command (0x38)

3526 The Get InfiniBand Link Status command allows the Management Controller to query the channel for the  
3527 IB Statistics.

3528 Implementation of this command is conditional and is required only for controllers supporting InfiniBand.

3529 Table 196 illustrates the packet format of the InfiniBand Link Status command.

3530 **Table 196 – Get InfiniBand Link Status command**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum (3..2)		Checksum (1..0)	
20..45	Pad			

### 3531 8.5.93 Get InfiniBand Link Status Response (0xB8)

3532 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get  
3533 InfiniBand Link Status command and send a response.

3534 The Get InfiniBand Link Status Response frame reports link width, logical and physical link states, and  
3535 the supported and the configured link speed of the port.

3536 Table 197 illustrates the packet format of the Get InfiniBand Link Status Response.

3537 **Table 197 – Get InfiniBand Link Status Response packet**

**Table 198 – InfiniBand Link Status definitions**

Name	Direction	Description
IB Link Active Width	TX	<p>When Link Type is InfiniBand and physical link is up, this field reflects the active link width. Otherwise this field returns 0b.</p> <p>Bit 0 – 1b = 1X link width</p> <p>Bit 1 - 1b = 2X link width</p> <p>Bit 2 - 1b = 4X link width</p> <p>Bit 3 - 1b = 8X link width</p> <p>Bits 7:4 Reserved</p>
IB Link Supported Width	RX	<p>When Link Type is InfiniBand, this field reflects the supported link widths. When Link Type is Ethernet, this field returns 0.</p> <p>Bit 0 - 1b = 1X link width is supported</p> <p>Bit 1 - 1b = 2X link width is supported</p> <p>Bit 2 - 1b = 4X link width is supported</p> <p>Bit 3 - 1b = 8X link width is supported</p> <p>Bits 7:4 Reserved</p>
Link Type	TX	<p>Reflects the configured link type.</p> <p>Bit 0 - 0b = Ethernet</p> <p>1b = InfiniBand</p>
Phys State	RX	<p>The physical link state as specified in IB spec (PortInfoPortPhysicalState)</p> <p>0x0 = Used when Link Type is Ethernet</p> <p>0x1 = Sleep</p> <p>0x2 = Polling</p> <p>0x3 = Disabled</p> <p>0x4 = PortConfigurationTraining</p> <p>0x5 = LinkUp</p> <p>0x6 = LinkErrorRecovery</p> <p>0x7 = PhyTest</p>
Logical Port State	TX	<p>The logical port state of the physical port as specified in IB spec (PortInfo.PortState)</p> <p>0x0: Used when Link Type is Ethernet</p> <p>0x1: Down</p> <p>0x2: Init</p> <p>0x3: Arm</p> <p>0x4: Active</p>

Name	Direction	Description
IB Link Active Speed	TX	<p>When Link Type is InfiniBand and the physical link is up, this field reflects the active link speed. Otherwise this field returns 0x00.</p> <p>Bit 0 - 1b = SDR</p> <p>Bit 1 - 1b = DDR</p> <p>Bit 2 - 1b = QDR</p> <p>Bit 3 - 1b = FDR10</p> <p>Bit 4 - 1b = FDR</p> <p>Bit 5 - 1b = EDR</p> <p>Bit 6 - 1b = HDR</p> <p>Bit 7 - 1b = NDR</p>
IB Link Supported Speed	RX	<p>When Link Type is InfiniBand, this field reflects the supported link speeds. When Link Type is Ethernet this field returns 0x00.</p> <p>Bit 0 - 1b = SDR</p> <p>Bit 1 - 1b = DDR</p> <p>Bit 2 - 1b = QDR</p> <p>Bit 3 - 1b = FDR10</p> <p>Bit 4 - 1b = FDR</p> <p>Bit 5 - 1b = EDR</p> <p>Bit 6 - 1b = HDR</p> <p>Bit 7 - 1b = NDR</p>

#### 3540 8.5.94 Get IB Statistics command (0x39)

3541 The Get IB Statistics command allows the Management Controller to query the channel for the IB  
3542 Statistics.

3543 Implementation of this command is conditional and is required only for controllers supporting InfiniBand.

3544 Table 199 illustrates the packet format of the Get IB Statistics Command.

3545 **Table 199 – Get IB Statistics Command**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

3546

### 8.5.95 Get IB Statistics Response ( 0xB9 )

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get IB Statistics command and send a response.

The Get IB Statistics Response frame reports a set of IB statistics from the channel. A value of 0xFFFFFFFF shall be used for any unsupported counter.

All counters shall be reset on Controller resets or power-cycles only.

Table 200 illustrates the packet format of the Get IB Statistics Response.

**Table 200 – Get IB Statistics Response packet**

	Bits			
Bytes	31..24	23..16	15..08	07..00

64..67	PortRcvSwitchRelayErrors			
68..71	LocalLinkIntegrityErrors			
72..75	ExcessiveBufferOverrun			
76..79	VL15Dropped			
80..83	Checksum (3..2)		Checksum (1..0)	

**Table 201 – IB Statistics Counter definitions**

Name	Direction	Description
PortXmitData	TX	Total number of data octets, divided by 4 (lanes), transmitted on all VLs.
PortRcvData	RX	Total number of data octets, divided by 4 (lanes), received on all VLs.
PortXmitPkts	TX	Total number of packets transmitted on all VLs from this port. This may include packets with errors.
PortRcvPkts	RX	Total number of packets (this may include packets containing Errors).

Name	Direction	Description
PortXmitWait	TX	Number of ticks during which the port had data to transmit but no data was sent during the entire tick (either because of insufficient credits or because of lack of arbitration).
PortXmitDiscard	TX	Total number of outbound packets discarded by the port because the port is down or congested.
SymbolErrorCounter	RX	Total number of minor link errors detected on one or more physical lanes.
LinkErrorRecoveryCounter	RX	Total number of times the Port Training state machine has successfully completed the link error recovery process.
LinkDownedCounter	RX	Total number of times the Port Training state machine has failed the link error recovery process and downed the link.
PortRcvErrors	RX	Total number of packets containing an error that were received on the port.
PortRcvRemotePhysicalErrors	RX	Total number of packets marked with the EBP delimiter received on the port.
PortRcvSwitchRelayErrors	RX	Total number of packets received on the port that were discarded because they could not be forwarded by the switch relay.
LocalLinkIntegrityErrors	RX	Number of times that the count of local physical errors exceeded the threshold specified by LocalPhyErrors.
ExcessiveBufferOverrun	RX	Number of times that OverrunErrors consecutive flow control update periods occurred, each having at least one overrun error.
VL15Dropped	RX	Number of incoming VL15 packets dropped due to resource limitations (e.g., lack of buffers) of the port.

### 3556 8.5.96 Settings Commit command ( 0x47 )

3557 The Settings Commit command is a package command used by the Management Controller to indicate  
 3558 that those previously programmed settings defined as persistent must now be written to non-volatile  
 3559 storage. It also indicates that any previously programmed individual settings that have dependencies on  
 3560 other settings (e.g., partition bandwidth) have been fully programmed and can be finalized and/or  
 3561 validated. Only those settings in commands that returned successful response/reason codes will be  
 3562 written to non-volatile storage.

3563 The MC can only be assured that settings have been persisted when this commit command has a  
 3564 successful completion. It is highly likely that execution of this command will result in a Delayed Response.  
 3565 The MC should assume that all settings that were sent but not committed are lost on losses of power,  
 3566 various types of resets as defined by the NC, return to initial states of any affected channel, etc. and must  
 3567 be resent after the interruption. The MC is ultimately responsible for ensuring its configuration settings  
 3568 have been properly received by the NC, therefore it is recommended that the MC monitor settings as  
 3569 appropriate.

3570 Table 202 illustrates the packet format of the Settings Commit command.

3571 **Table 202 – Settings Commit command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

### 3572 8.5.97 Settings Commit response (0xC7)

3573 The package shall, in the absence of an error, always accept the Settings Commit command and send  
3574 the response packet shown in Table 203.

3575 Currently no command-specific reason code is identified for this response.

3576 **Table 203 – Settings Commit response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

### 3577 8.5.98 Get ASIC Temperature (0x48)

3578 The Get ASIC Temperature command allows the Management controller to query for temperature values  
3579 from the Controller's on-chip thermal sensor(s) or alternately from attached (external) devices.

3580 The Get ASIC Temperature command is defined as both a package level command and a channel  
3581 command. This means the command can be either addressed to the package (that is, the command is  
3582 sent with the Internal Channel ID set to 0x1F) or addressed to a specific channel in the package.

3583 When sent as a package command, the internal temperature of the controller is returned. If the controller  
3584 has multiple internal temperature sensors, the highest measured temperature with respect to its threshold  
3585 shall be returned.

3586 In cases where there are other devices connected to the controller that can also report silicon  
3587 temperature via the controller (such as one or more external PHYs), then the channel version of the  
3588 command is used, and the response contains the temperature data and threshold from the external  
3589 device on that channel. Multiple sensor implementations in the external device shall be handled as  
3590 described above.

3591 Table 204 illustrates the packet format of the Get ASIC Temperature Command.

3592 **Table 204 – Get ASIC Temperature Command packet**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Reserved			
20..23	Checksum			
24..45	Pad			

3593 **8.5.99 Get ASIC Temperature Response ( 0xC8 )**

3594 The package shall, in the absence of a checksum error or identifier mismatch, always accept the Get  
 3595 ASIC Temperature Command and send a response.

3596 Table 205 illustrates the packet format of the Get ASIC Temperature Response.

3597 **Table 205 – Get ASIC Temperature Response packet**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Maximum temperature		Current temperature	
24..27	Checksum			
28..45	Pad			

3598 **8.5.99.1 Maximum Temperature Value**

3599 This value is the maximum T-Diode temperature limit in degrees Celsius at which the controller can  
 3600 operate at full load for its rated service lifetime. The value should be derated to take measurement  
 3601 tolerance into account. The value shall be reported as a signed 16-bit integer.

3602 **8.5.99.2 Current Temperature Value**

3603 This value is the highest current real-time temperature of the ASIC sensors in degrees Celsius. The value  
 3604 shall be reported as a signed 16-bit integer.

3605 **8.5.100 Get Ambient Temperature ( 0x49 )**

3606 The Get Ambient Temperature command allows the Management controller to query for temperature  
 3607 values from ambient temperature sensor(s) attached to the Controller.

3608 The Get Ambient Temperature command is defined as a package command.

3609 Controllers that do not support ambient temperature sensors should not implement this command.

3610 Table 206 illustrates the packet format of the Get Ambient Temperature command.

3611

Table 206 – Get Ambient Temperature command packet

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Reserved			
20..23	Checksum			
24..45	Pad			

**8.5.101 Get Ambient Temperature Response ( 0xC9 )**

The Package shall, in the absence of a checksum error or identifier mismatch, always accept the Get Ambient Temperature Command and send a response.

Table 207 illustrates the packet format of the Get Ambient Temperature Response.

Table 207 – Get Ambient Temperature Response packet

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Temperature3 value	Temperature2 Value	Temperature1 Value	Number of sensors
24..27	Checksum			
28..45	Pad			

**8.5.101.1 Temperature Value**

This value (zero or more as specified by the Number of sensors field) is the real time ambient temperature reported in degrees Celsius. The value shall be reported as a signed 8-bit integer.

**8.5.102 Get Transceiver Temperature ( 0x4A )**

The Get Transceiver Temperature command allows the Management controller to query for the real time temperature value and thresholds of the (optical) transceiver attached to the channel. Implementations that do not support any type of temperature reporting module, such as a Base-T or backplane Ethernet adapter, should not implement this command.

Table 208 illustrates the packet format of the Get Transceiver Temperature Command.

3628 **Table 208 – Get Transceiver Temperature Command Packet**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Reserved			
20..23	Checksum			
24..45	Pad			

3629 **8.5.103 Get Transceiver Temperature Response (0xCA)**

3630 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get  
3631 Transceiver Temperature command and send a response.

3632 The Get Transceiver Temperature Response frame contains the current temperature of the attached  
3633 module and the high side temperature thresholds.

3634 Definitions and interpretation of the data fields in the response are defined in the relevant SFF or MSA  
3635 specification (e.g., [SFF-8472](#), [SFF-8436](#), [SFF-8636](#), [CMIS 4.0](#), 5.x, etc.) for the transceiver. 16-bit values  
3636 are encoded as one contiguous entity with the most significant bit in bit 15 (or 31) and least significant bit  
3637 in bit 0 (or 16) in the response packet. The Controller is not expected to modify the data read from the  
3638 transceiver.

3639 In cases where the transceiver supports more than one channel, each channel shall provide a response  
3640 when queried.

3641 The reason code - *Information not available* - shall be used if the transceiver is not present, does not  
3642 provide temperature data or if the command is issued before the transceiver has not yet achieved power  
3643 up state.

3644 Table 209 illustrates the packet format of the Get Transceiver Temperature Response.

3645 **Table 209 – Get Transceiver Temperature Response packet**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Temp High Alarm Threshold		Temp High Warning Threshold	
24..27	Temperature Value		Reserved	
28..31	Checksum			

3646 **8.5.104 Thermal Shutdown Control Command (0x4B)**

3647 The Thermal Shutdown Control command allows the Management controller to query for the state of or  
3648 alternatively set or reset the enablement state of the NC's thermal self-shutdown feature. NCs shall  
3649 indicate the implementation state of this feature in the Get Capabilities command response bit 7 and  
3650 implement this command/response only when the feature is present. .

3651 The Thermal Shutdown Control command is defined as a package-level command and is sent with the  
3652 Internal Channel ID set to 0x1F.

3653 Table 210 illustrates the packet format of the Thermal Shutdown Control Command.

3654 **Table 210 – Thermal Shutdown Control Command packet**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Reserved			Command
20..23	Checksum			
24..45	Pad			

#### 3655 8.5.104.1 Command Field

3656 The value specified in this field defines the action required for the NC's shutdown feature.

3657 **Table 211 – Command field bit definitions**

Value	Description	Value Description
0	Disable	Thermal self-shutdown shall be disabled on the device
1	Enable	Thermal self-shutdown shall be enabled on the device
2	Query	The currently configured shutdown setting shall be returned
others	Reserved	None

#### 3658 8.5.105 Thermal Shutdown Control Response (0xCB)

3659 The package shall, in the absence of a checksum error or identifier mismatch, always accept the Thermal  
3660 Shutdown Control Command and send a response.

3661 The Operating State status provided in the response shall be confirming the state after the execution of  
3662 the command. If the Config Control state is set to Read-only, any command to enable or disable the  
3663 feature shall be failed with the Parameter Is Invalid reason code. The other fields shall be included in the  
3664 response with their current setting.

3665 Table 212 illustrates the packet format of the Thermal Shutdown Control Response.

3666 **Table 212 – Thermal Shutdown Control Response packet**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Reserved	Reserved	Status	Shutdown temperature
24..27	Checksum			
28..45	Pad			

3667 **8.5.105.1 Shutdown Temperature Value**

3668 This value is the integer temperature value in degrees Celsius at which the NC will shut itself down when  
 3669 reached.

3670 **8.5.105.2 Status Field**

3671 The value returned in this field is the enablement status of the shutdown feature.

3672 **Table 213 – Status field bit definitions**

Bit	Description	Value Description
0	Operating State	0b = Thermal self-shutdown is disabled on the device 1b = Thermal self-shutdown is enabled on the device
others	Reserved	None

3673 **8.5.106 Get Inventory Information command (0x4E)**

3674 The Get Inventory Information command may be used by the Management Controller to query the  
 3675 Network Controller for defined inventory information about the NC.

3676 This command is defined as a package command.

3677 Table 214 illustrates the packet format of the Inventory Information command.

3678 **Table 214 – Get Inventory Information command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

**8.5.107 Get Inventory Information response (0xCE)**

The package shall, in the absence of an error, always accept the Get Inventory Information command and send the response packet shown in Table 215. The value fields are defined as non-terminated ASCII strings except for the Manufacturing Timestamp which is timestamp104 as defined in [DSP0240](#).

Currently no command-specific reason code is identified for this response.

**Table 215 – Get Inventory Information response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code

	...			
	Checksum			
	Pad			

**8.5.107.1 Inventory Information Type-Length-Value fields**

The Type definitions for the inventory elements are defined below.

**Table 216 – Inventory Information Type-Length field**

Bit Position	Field Description	Value Description
7..0	Attribute Name/Type	0x0 = Manufacturer 0x1 = Product / Model 0x2 = Version 0x3 = Part Number 0x4 = Serial Number 0x5 = Manufacturing Timestamp104  0x6-0x7F = Reserved 0x80-0xAF = Reserved for Manufacturer Use 0xB1 = Vendor/OEM 0xB1 = Product Name 0xB2 = SKU / Part Number 0xB3 = Version 0xB4-0xFF = Reserved for OEM use
15..8	Length	Length in bytes of the field

**8.5.108 Set Pass-through Mode Control Command ( 0x33 )**

The Set Pass-through Mode Control command allows the Management controller to enable and disable specified data paths for Pass-through data on the channel when supported by the NC.

Implementation of this command is conditional depending on the type of device and its feature set. For non-Ethernet devices, this command would only be implemented if some type of Pass-thru is supported. For Ethernet NCs, support of either Host-BMC Pass-through or embedded CPU-BMC Pass-through functionality mandates the implementation of this command. Network-BMC Pass-through is traditional NC-SI Pass-through (required in NC-SI), whereas Host-BMC Pass-through is defined to be a network path between the Host and the BMC via the NC-SI Interface. Embedded CPU-BMC Pass-through is defined as a network path that is defined between the BMC and a compute engine or other entity on the network adapter. Further definition of these interfaces is beyond the scope of this specification.

The Host-BMC Pass-through, Network-BMC Pass-through and embedded CPU-BMC Pass-through controls specified in this command act as masks in conjunction with the existing Enable Channel and Enable Channel TX commands. The existing Pass-through MAC address and filtering control methods are simply extended to all defined data paths when configured. No additional filters or MACs are provided.

Table 217 illustrates the packet format for the Set Pass-through Mode Control Command.

**Table 217 – Set Pass-through Mode Control Command**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Reserved	Reserved	Pass-through Type	Reserved
20..23	Checksum			
24..45	Pad			

**8.5.108.1 Pass-through Type Field**

The Pass-through Type field indicates which Pass-through data path is to be enabled or disabled as described in Table 218.

**Table 218 – Pass-through Type definitions**

Bit	Field Description	Value Description
0	Network-BMC Pass-through traffic	0b = Disallowed 1b = Allowed (default)
1	Host-BMC Pass-through traffic	0b = Disallowed (default) 1b = Allowed
2	Embedded CPU -BMC Pass-through traffic	0b = Disallowed (default) 1b = Allowed
7..3	Reserved	0b

### 3710 8.5.109 Set Pass-through Mode Control Response (0xB3)

3711 In the absence of any errors, the channel shall process and respond to the Set Pass-through Mode  
3712 Control command and send the response packet shown in Table 219 – Set Pass-through Mode Control  
3713 Response Packet.

3714 **Table 219 – Set Pass-through Mode Control Response Packet**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
28..31	Checksum			
32..45	Pad			

### 3715 8.5.110 Get Pass-through Mode Command (0x34)

3716 The Get Pass-through Mode command allows the Management controller to query the Network Controller  
3717 for the current state of the Pass-through data paths supported by the channel. Implementation of this  
3718 command is required if the Set Pass-through Mode Control command is implemented.

3719 Table 220 illustrates the packet format for the Get Pass-through Mode Control command.

3720 **Table 220 – Get Pass-through Mode Command Packet**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

### 3721 8.5.111 Get Pass-through Mode Response (0xB4)

3722 In the absence of any errors, the channel shall process and respond to the Get Pass-through Mode  
3723 Control command and send the response packet shown in Table 221.

3724 **Table 221 – Get Pass-through Mode Response Packet**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Reserved	Reserved	Pass-through Mode Status	Pass-through Mode Capability
24..27	Checksum			
28..45	Pad			

**8.5.111.1 Pass-through Mode Status Field**

The Pass-through Mode Status field indicates which Pass-through data path(s) are currently allowed.

**Table 222 – Pass-through Type definitions**

Bit	Field Description	Value Description
0	Network-BMC Pass-through traffic	0b = Currently Disallowed 1b = Currently Allowed (default)
1	Host-BMC Pass-through traffic	0b = Currently Disallowed (default) 1b = Currently Allowed
2	embedded CPU -BMC Pass-through traffic	0b = Currently Disallowed (default) 1b = Currently Allowed
7..3	Reserved	0b

**8.5.111.2 Pass-through Mode Capability Field**

The Pass-through Mode Capability field indicates which Pass-through Mode data path(s) are supported by the implementation.

**Table 223 – Pass-through Type definitions**

Bit	Field Description	Value Description
0	Network-BMC Pass-through traffic	0b = Not Supported 1b = Supported
1	Host-BMC Pass-through traffic	0b = Not Supported 1b = Supported
2	embedded CPU -BMC Pass-through traffic	0b = Not Supported 1b = Supported
7..3	Reserved	0b

**8.5.112 Transmit Data to NC command (0x4C)**

The Transmit Data to NC command is a package command that allows the MC to transfer an opaque block of data of up to 16 MB to the NC. The transfer can be initiated by the MC itself or in response to the reception of the Transfer Data AEN. In the latter case, the Total Length of Transfer and Data Handle fields (if provided) should be populated from the AEN fields. If the requested Data Handle is not supported, then the Abort opcode shall be used. Blocks of data that exceed the data space available in one NC-SI frame will be broken down into multiple transfers that comply with NC-SI RBT frame size. When multiple transfers are used:

- Transmission ordering shall be maintained
- All chunks shall be an integer multiple of 32 bits, (i.e., double-word aligned), except for the last which may include padding to make it double-word aligned
- If the NC detects a transfer error it may request a retransmission of the active chunk, but no other

- 3745       • Any processing of the block of data will only after the successful reception of all transmitted  
3746 chunks

3747 The MC and the NC both have the ability to abort the transfer at any time during the transfer by use of the  
3748 proper opcode or reason code respectively. If the NC loses transfer context due to being reset or other  
3749 event, or if it detects an out of order chunk number being specified in the command, it shall abort the  
3750 transfer. Any data transfer that is aborted is deemed to have failed and cannot be resumed. The MC may  
3751 attempt to repeat the transfer as a new transfer sequence.

3752 Only one active transfer sequence (transmit or receive) is supported at a given time.

3753 Table 224 illustrates the packet format of the Transmit Data to NC command.

3754                   **Table 224 – Transmit Data to NC command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Total Length of Transfer (Bytes)			Opcode
20..23	Offset		Chunk Length	
24..27	Data Handle/Chunk Number			
	Chunk or Part of Data			
	Checksum			
	Pad			

#### 3755   **8.5.112.1 Total Length of Transfer field**

3756 Length in bytes of the entire data block to be transferred.

#### 3757   **8.5.112.2 Opcode field**

3758                   **Table 225 – Opcode field format**

Value	Description	Value Description
0	Initial Chunk	First block of data in the transfer
1	Final Chunk	Last block of data in the transfer
2	Middle Chunk	Intermediate block of data in the transfer
3	Abort Transfer	Terminate the transfer
others	Reserved	

#### 3759   **8.5.112.3 Offset**

3760 Offset of the current transfer within the larger data block.

#### 3761   **8.5.112.4 Chunk Length**

3762 The length in bytes of the chunk being transferred with this command.

3763 **8.5.112.5 Data Handle/Chunk number**

3764 For the first chunk being transferred (Initial Chunk Opcode), this is an identifier of the block of data being  
 3765 transferred. For subsequent chunk transfers it is a sequentially incrementing count for the chunk being  
 3766 transferred (equal to 2 for the second chunk transfer, 3 for the third, etc.).

3767 **8.5.113 Transmit Data to NC response (0xCC)**

3768 The package shall, in the absence of a checksum error or identifier mismatch, always accept the Transmit  
 3769 Data to NC command and send a response.

3770 Table 226 illustrates the packet format of the Transmit Data to NC command response.

3771 There are command-specific reason codes identified for this response (see Table 227).

3772 **Table 226 – Transmit Data to NC response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Checksum			
24..45	Pad			

3773 **Table 227 – Transmit Data to NC command-specific reason codes**

Value	Description	Comment
0x4C01	Abort Transfer	Returned when the NC is terminating the transfer for unspecified reason
0x4C02	Unknown Data Handle	Specified Data Handle is not supported
0x4C03	Sequence count error	Chunk Number received is not consecutive with the previous number received. Also results in an aborted transfer.
0x4C04	Length error	Incorrect chunk length
0x4C05	Insufficient Storage	NC cannot process or store a data block of Total Length
0x4C06	Invalid Handle Value	Data Handle is invalid or not supported

3774 **8.5.114 Receive Data from NC command (0x4D)**

3775 The Receive Data from NC command is a package command that allows the MC to receive an opaque  
 3776 block of data of up to 16 MB from the NC. Blocks of data that exceed the data space available in one NC-  
 3777 SI frame will be broken down into multiple transfers that comply with NC-SI RBT frame size. When  
 3778 multiple transfers are used:

- 3779 • Reception ordering shall be maintained
- 3780 • All chunks shall be an integer multiple of 32 bits, (i.e., double-word aligned), except for the last  
 3781 which may include padding to make it double-word aligned
- 3782 • If the MC detects a transfer error it may request a retransmission of the active chunk, but no  
 3783 other

- 3784       • Any processing of the block of data will only after the successful reception of all transmitted  
3785 chunks

3786 The MC and the NC both have the ability to abort the transfer at any time during the transfer by use of the  
3787 proper opcode or reason code respectively. If the NC loses transfer context due to being reset or other  
3788 event, or if it detects an out of order chunk number being specified in the command, it shall abort the  
3789 transfer. Any data transfer that is aborted is deemed to have failed and cannot be resumed. The MC may  
3790 attempt to repeat the transfer as a new transfer sequence.

3791 Only one active transfer sequence (transmit or receive) is supported at a given time.

3792 Table 228 illustrates the packet format of the Receive Data from NC command.

3793                   **Table 228 – Receive Data from NC command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
	Reserved			Opcode
	Offset		Reserved	
	Data Handle/Chunk Number			
16..19	Checksum			
20..45	Pad			

#### 3794   **8.5.114.1 Total Length of Transfer field**

3795 Length in bytes of the entire data block to be transferred.

#### 3796   **8.5.114.2 Opcode field**

3797                   **Table 229 – Opcode field format**

Value	Description	Value Description
0	Initial Chunk	Request for the first chunk of the transfer to be returned
1	Reserved	
2	Next Chunk	Request for the next chunk of the transfer to be returned
3	Abort Transfer	Termination of transfer by MC
others	Reserved	

#### 3798   **8.5.114.3 Offset field**

3799 Offset of the current transfer within the larger data block.

#### 3800   **8.5.114.4 Chunk Length field**

3801 The length in bytes of the chunk being requested by this command.

**8.5.114.5 Data Handle/Chunk number field**

For the first chunk being requested (Initial Chunk Opcode), this is an identifier of the block of data being requested. For subsequent chunk transfers it is a sequentially incrementing count for the chunk being transferred (equal to 2 for the second chunk transfer, 3 for the third, etc.).

**8.5.115 Receive Data from NC response (0xCD)**

The package shall, in the absence of a checksum error or identifier mismatch, always accept the Receive Data from NC command and send a response.

Table 230 illustrates the packet format of the Receive Data from NC command response.

**Table 230 – Receive Data from NC response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Total Length of Transfer (Bytes)			Opcode
24..27	Offset		Chunk Length	
	Data Handle/Chunk Number			
	Data			
	Checksum			
	Pad			

**8.5.115.1 Total Length of Transfer field**

Length in bytes of the entire data block to be transferred

**8.5.115.2 Opcode field****Table 231 – Opcode field format**

Value	Description	Value Description
0	Initial Chunk	First block of data in the transfer
1	Final Chunk	Last block of data in the transfer
2	Middle Chunk	Intermediate block of data in the transfer
3	Abort Transfer	Terminate the transfer
others	Reserved	

**8.5.115.3 Offset field**

Offset of the current transfer within the larger data block

**8.5.115.4 Chunk Length field**

The length in bytes of the chunk being requested by this command.

3819 **Table 232 – Receive Data from NC command-specific reason codes**

Value	Description	Comment
0x4D01	Abort Transfer	NC cannot proceed with transfer
0x4D02	Sequence count error	Chunk Number requested is not consecutive with the previous number transmitted
0x4D03	Final Chunk of Transfer	Sent with Response Code 0000 to indicate the last chunk of the transfer
0x4C06	Invalid Handle Value	Data Handle is invalid or not supported

3820 **8.5.116 SPDM command (0x60)**

3821 The SPDM command is used by the Management controller in RBT implementations to encapsulate and  
 3822 send a SPDM payload as defined in [DSP0274](#) to the NC or alternately receive an encapsulated SPDM  
 3823 payload from the NC.

3824 The SPDM payload must be smaller than the maximum NC-SI payload allowed over RBT. Payloads that  
 3825 exceed the RBT limits shall use SPDM's native multi-part transfer mechanism. Polling mode shall be used  
 3826 to transfer each part of a multi-part transfer from the NC.

3827 The command response may be a long running command due to the nature of some SPDM tasks.

3828 The SPDM command is defined as a package command.

3829 This command and response are not supported on NC-SI over MCTP.

3830 Table 233 illustrates the packet format of SPDM command.

3831 **Table 233 – SPDM command packet**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	SPDM Version	Request Code	Param 1	Param 2
20..	SPDM Message Payload			
	Checksum			
	Pad			

3832 **8.5.117 SPDM Response (0xE0)**

3833 The Package shall, in the absence of a checksum error or identifier mismatch, always accept the SPDM  
 3834 Command and send a response.

3835 Table 234 illustrates the packet format of the SPDM Response.

3836

**Table 234 – SPDM Response packet**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	SPDM Version	Completion Code	Param 1	Param 2
24..	SPDM Response Payload			
	Checksum			
	Pad			

**3837 8.5.118 Query Pending NC SPDM Request (0x61)**

3838 The Query Pending NC SPDM Request may be used by the Management Controller in RBT  
 3839 implementations to read the status of pending SPDM requests which the NC needs to send to the MC.  
 3840 Only one SPDM request can be handled by a Pending SPDM Request instance. When multiple requests  
 3841 are pending in the NC, each will be handled independently and the order at which requests are provided  
 3842 to the MC is decided by the NC.

3843 The Query Pending NC SPDM command is defined as a package command.

3844 This command and response are not supported on NC-SI over MCTP.

3845 Table 235 illustrates the packet format of the Query Pending NC SPDM Request command.

3846

**Table 235 – Query Pending NC SPDM Request packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

**3847 8.5.119 Query Pending NC SPDM Request Response (0xE1)**

3848 In the event there are no pending requests, the command shall execute successfully and return with no  
 3849 SPDM payload. Currently no command-specific reason code is identified for this response (see Table  
 3850 248).

3851 Table 236 illustrates the packet format of the Query Pending NC SPDM Request Response.

3852

**Table 236 – Query Pending NC SPDM Request Response Packet Format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..	SPDM Version	Request Code	Param 1	Param 2

Bytes	Bits			
	31..24	23..16	15..08	07..00
	SPDM Message Payload + Payload Pad (zero or more bytes)			
	Checksum			
	Pad			

3853

**Table 237 – Query Pending NC SPDM Request Response parameters**

Name	Meaning
SPDM Version	Optional, included only when there is a pending request
Request Code	Optional, included only when there is a pending request
Param1	Optional, included only when there is a pending request
Param2	Optional, included only when there is a pending request
SPDM Message Payload	Optional, included only when there is a pending request

**3854 8.5.120 Send NC SPDM Reply (0x62)**

3855 The Reply Pending SPDM command may be used by the Management Controller to provide the SPDM  
 3856 command response to previously read SPDM command from the NC. The response to this command  
 3857 further provides indication to the MC regarding additional pending SPDM NC commands.

3858 Table 238 illustrates the packet format of the Send NC SPDM Reply command.

3859

**Table 238 – Send NC SPDM Reply packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	SPDM Version	Completion Code	Param 1	Param 2
20..	SPDM Message Payload (zero or more bytes) + Payload Pad			
	Checksum			
	Pad			

**3860 8.5.121 Send NC SPDM Reply Response (0xE2)**

3861 Currently no command-specific reason code is identified for this response.

3862 Table 239 illustrates the packet format of the Send NC SPDM Reply command.

3863

**Table 239 – Send NC SPDM Reply Response packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	

Bytes	Bits			
	31..24	23..16	15..08	07..00
20..23	Reserved			Flags
24..27	Checksum			
28..45	Pad			

Table 240 – Reply NC SPDM Response parameters

Name	Meaning
Flags bit 0 – Pending request	0b – No additional pending SPDM command from NC to MC  1b – The NC has additional pending SPDM command to the MC
Flags bits 7:1 - Reserved	Reserved, always return 0.

### 8.5.122 Query and Set OEM AEN command ( 0x54 )

The channel command Query and Set OEM AEN is used by the Management controller when sets of different OEM AENs, identified by the OEM's IANA value, are simultaneously supported by a NC. It allows the MC to query the channel for the active OEM AEN set as well as the other OEM AEN sets that are supported. The MC can then configure a particular IANA as the active one for subsequent issues of the Enable AEN command.

Implementation of this command is optional for those NCs that support only one set of OEM AENs

Implementation of this command is required when the NC has implemented multiple sets of OEM AENs and allows the MC to select a set that is different than the default

The NC may allow AENs from multiple sets to be simultaneously enabled through the successive uses of this command and AEN Enable

The NC shall interpret a null IANA in the received command as a request for the list of OEM AEN sets and shall not change the active set.

The Query and Set OEM AEN command is defined as a channel command.

Table 241 illustrates the packet format of Query and Set OEM AEN command.

Table 241 – Query and Set OEM AEN command packet

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	IANA Field			
20..23	Checksum			
24..45	Pad			

### 3881 8.5.123 Query and Set OEM AEN Response (0xD4)

3882 The Channel shall, in the absence of a checksum error or identifier mismatch, always accept the Query  
3883 and Set OEM AEN Command and send a response.

3884 For each supported OEM IANA, #1 through #n, three fields are required: the identifying IANA field, and  
3885 the 16-bit Enabled AENs and Supported AENs fields that correspond 1:1 to bits 31..16 in the AEN Control  
3886 Field of the AEN Enable command.

3887 Table 242 illustrates the packet format of the Query and Set OEM AEN Response.

3888 **Table 242 – Query and Set OEM AEN Response packet**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Reserved	Reserved	Reserved	# of IANAs
24..27	Configured IANA			
28..31	IANA # 1			
32..35	IANA # 1 Enabled AENs		IANA # 1 Supported AENs	
	IANA # 2			
	...			
	Checksum			
	Pad			

#### 3889 8.5.123.1 # of IANAs field

3890 An integer value representing the number of OEM AEN sets supported by the NC.

#### 3891 8.5.123.2 Configured IANA field

3892 The IANA representing the currently enabled OEM AEN set for configuration by subsequent Enable OEM  
3893 AEN commands. If a valid IANA was sent in the command, the response shall confirm the change to that  
3894 IANA set. If the sent IANA was not valid, the previously configured IANA set shall remain active.

#### 3895 8.5.123.3 IANA #n field

3896 The identifier for the n<sup>th</sup> OEM AEN set supported by the NC.

#### 3897 8.5.123.4 IANA #n Enabled AENs field

3898 A bitmap showing the currently enabled AENs from the IANA #n's set of supported AENs.

#### 3899 8.5.123.5 IANA #n Supported AENs field

3900 A bitmap showing the supported OEM AENs in the IANA #n's AEN set.

3901 **8.5.124 OEM command ( 0x50 )**

3902 The OEM command may be used by the Management Controller to request that the channel provide  
 3903 vendor-specific information. The [Vendor Enterprise Number](#) is the unique MIB/SNMP Private Enterprise  
 3904 number assigned by IANA per organization. Vendors are free to define their own internal data structures  
 3905 in the vendor data fields.

3906 Table 243 illustrates the packet format of the OEM command.

3907 **Table 243 – OEM command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Manufacturer ID (IANA)			
20...	Vendor-Data			
	NOTE: The optional checksum is unspecified for the OEM command. OEMs supporting checksum validation for NC-SI commands may include the checksum in the OEM specific payload for the command and response.			

3908 **8.5.125 OEM response ( 0xD0 )**

3909 The channel shall return the “Unknown Command Type” reason code for any unrecognized enterprise  
 3910 number, using the packet format shown in Table 244. If the command is valid, the response, if any, is  
 3911 allowed to be vendor specific. The 0x8000 range is recommended for vendor-specific code.

3912 Table 244 illustrates the packet format of the OEM command response.

3913 **Table 244 – OEM response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	Manufacturer ID (IANA)			
24...	Return Data (Optional)			

**8.5.126 PLDM Request (0x51)**

The PLDM Request Packet may be used by the Management Controller to send PLDM commands over NC-SI/RBT. This command may be targeted at the entire package or a specific channel. It is expected that the MC will use PLDM Request command 0x51 to query the supported PLDM commands, before using Query Pending NC PLDM Request command.

Table 245 illustrates the packet format of the PLDM Request Packet over NC-SI/RBT.

**Table 245 – PLDM Request packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	PLDM Message Common Fields			
20..	PLDM Message Payload (zero or more bytes) + Payload Pad )			
..	Checksum			
..	Pad			

Refer to the PLDM Base specification (DSP0240) for details on the PLDM messaging control and discovery commands.

**8.5.127 PLDM Response (0xD1)**

The PLDM Response Packet may be used by the Network Controller to send PLDM responses over NC-SI/RBT. The package shall, in the absence of a checksum error or identifier mismatch, always accept the PLDM Request Command and send a response.

Table 246 illustrates the packet format of the PLDM command response.

**Table 246 – PLDM Response packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Response Code		Reason Code	
20..23	PLDM Message Common Fields			PLDM Completion Code
24..	PLDM Message Payload (zero or more bytes) + Payload Pad			
..	Checksum			
..	Ethernet Packet Pad			

Refer to the PLDM Base specification ([DSP0240](#)) for details on the PLDM Response Messages.

Note that the NC-SI PLDM Response (0xD1) response/reason codes are only used to report the support, success, or failure of the PLDM Request command (0x51) at the NC-SI over RBT messaging layer. The PLDM Completion Code is used for determining the success or failure of the encapsulated PLDM Commands at the PLDM messaging layer.

**8.5.128 Query Pending NC PLDM Request (0x56)**

The Query Pending NC PLDM Request may be used by the Management Controller to read the status of pending PLDM commands which the NC needs to send to the MC. Only one PLDM request can be handled by a Pending PLDM Request instance. When multiple requests are pending in the NC, each will be handled independently and the order at which requests are provided to the MC is decided by the NC.

Implementations using PLDM over RBT, where the NC has to send PLDM commands to the MC, shall support this command.

Table 247 illustrates the packet format of the Query Pending NC PLDM Request command.

**Table 247 – Query Pending NC PLDM Request packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

**8.5.129 Query Pending NC PLDM Request Response (0xD6)**

In the event there are no pending requests, the command shall execute successfully and return with no PLDM payload. Currently no command-specific reason code is identified for this response (see Table 248).

Table 248 illustrates the packet format of the Query Pending NC PLDM Request Response.

**Table 248 – Query Pending NC PLDM Request Response Packet Format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..	PLDM Message Common Fields			PLDM Message Payload
	PLDM Message Payload + Payload Pad (zero or more bytes)			
	Checksum			
	Pad			

**Table 249 – Query Pending NC PLDM Request Response parameters**

Name	Meaning
PLDM Message Common fields	Optional, included only when there is a pending request
PLDM Message Payload	Optional, included only when there is a pending request

**8.5.130 Send NC PLDM Reply (0x57)**

The Reply Pending PLDM command may be used by the Management Controller to provide the PLDM command response to previously read PLDM command from the NC that requires a response (Rq = 1, D = 0 in PLDM Message Common Fields). The response to this command further provides indication to the MC regarding additional pending PLDM NC commands.

Table 250 illustrates the packet format of the Send NC PLDM Reply command.

**Table 250 – Send NC PLDM Reply packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	PLDM Message Common Fields			PLDM Completion Code
20..	PLDM Message Payload (zero or more bytes) + Payload Pad			
	Checksum			
	Pad			

**8.5.131 Send NC PLDM Reply Response (0xD7)**

Currently no command-specific reason code is identified for this response.

Table 251 illustrates the packet format of the Send NC PLDM Reply command.

**Table 251 – Send NC PLDM Reply Response packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Reserved			Flags
24..27	Checksum			
28..45	Pad			

**Table 252 – Reply NC PLDM Response parameters**

Name	Meaning
Flags bit 0 – Pending request	0b – No additional pending PLDM command from NC to MC  1b – The NC has additional pending PLDM command to the MC
Flags bits 7:1 - Reserved	Reserved, always return 0.

**8.5.132 Transport-specific AEN Enable command (0x55)**

Network Controller implementations shall support this command on the condition that the Network Controller generates one or more RBT-specific AENs defined in this specification or other NC-SI bindings such as [DSP0261](#). The AEN Enable command enables and disables the different transport specific AENs supported by the Network Controller. The Network Controller shall copy the AEN MC ID field from the AEN Enable command into the MC ID field in every subsequent AEN sent to the Management Controller as defined in AEN Enable command

Table 253 illustrates the packet format of the Enable Transport-specific AENs command.

**Table 253 – Transport-specific AEN Enable command packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Reserved		Transport-specific AENs enable	
20..23	Checksum			
24..45	Pad			

**Table 254 – Transport-specific AEN enable field format**

Bit Position	Field Name	Value Description
0	Medium Change AEN Control (0x70)	0b = Disable Medium Change AEN 1b = Enable Medium Change AEN Relevant only for NC-SI/MCTP
1	Pending PLDM Request AEN (0x71)	0b = Disable Pending PLDM Request AEN 1b = Enable Pending PLDM Request AEN Relevant only for PLDM over NC-SI control over RBT
2	Pending SPDM Request AEN (0x72)	0b = Disable Pending SPDM Request AEN 1b = Enable Pending SPDM Request AEN Relevant only for SPDM over NC-SI control over RBT
3..15	Reserved	Reserved

**8.5.133 Transport-specific AENs Enable Response (0xD5)**

In the absence of any error, the package shall process and respond to the Transport-specific AEN Enable command by sending the response packet and payload shown in Table 255.

3976 **Table 255 – Transport-specific AEN Enable Response packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
...	Pad			

3977 **8.5.134 Get MC MAC Address command (0x58)**

3978 A network controller may provision MAC addresses for Out-Of-Band (OOB) management traffic. These  
 3979 MAC addresses are not visible to the host(s). Get MC MAC Address is used to discover MAC addresses  
 3980 provisioned on the network controller for the MC. Get MC MAC Address is a channel-specific command.  
 3981 For multiport devices, it is expected that the MC queries provisioned MC MAC Addresses on each  
 3982 channel individually.

3983 Table 256 illustrates the packet format of the Get MC Address Command.

3984 **Table 256 – Get MC MAC Address command packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Checksum			
20..45	Pad			

3985 **8.5.135 Get MC MAC Address response (0xD8)**

3986 In the response of Get MC MAC Address command, the network controller provides the information about  
 3987 the provisioned MAC address(es) for the MC on that channel. The NC shall, in the absence of an error,  
 3988 always accept the Get MC MAC Address command and send the response packet shown in Table 257.  
 3989 Currently no command-specific reason code is identified for this response.

3990 **Table 257 – Get MC MAC Address response packet format**

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	NC-SI Header			
16..19	Response Code		Reason Code	
20..23	Address Count	Reserved		
Variable	Addr 1 Byte 5	Addr 1 Byte 4	Addr 1 Byte 3	Addr 1 Byte 2
	Addr 1 Byte 1	Addr 1 Byte 0	Addr 2 Byte 5	Addr 2 Byte 4
	...			
	...		Pad (if needed)	

3991   **8.5.135.1 Address Count**

3992   This field shall be set to the number of MC MAC addresses provisioned on the channel.

3993   **8.5.135.2 Reserved**

3994   This field shall be set to 0 by the network controller and shall be ignored by the management controller.

3995   **8.5.135.3 Addr i Byte j**

3996   This field shall be set to the value of j<sup>th</sup> byte (1 ≤ j ≤ 6) of i<sup>th</sup> provisioned MC MAC address.

3997   **8.5.135.4 Pad**

3998   If the number of MC MAC addresses is an odd number, then 2 bytes of the Pad field shall be present at  
3999   the end of the payload to align the payload on a 32-bit boundary. If present, each byte of the Pad field  
4000   shall be set to 0x00.

4001   If the number of MC MAC addresses is an even number, then 0 bytes of Pad shall be present.

4002   **8.5.136 Get Package UUID command (0x52)**

4003   The Get Package UUID command may be used by the Management Controller to query Universally  
4004   Unique Identifier (UUID), also referred to as a globally unique ID (GUID), of the Network Controller over  
4005   NC-SI/RBT. This command is targeted at the package. This command can be used by the MC to  
4006   correlate endpoints used on different NC-SI transports (e.g., RBT, MCTP).

4007   Table 258 illustrates the packet format of the Get Package UUID Command over NC-SI/RBT.

4008                   **Table 258 – Get Package UUID command packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	NC-SI Control Packet Header			
16..19	Checksum			
20..45	Pad			

4009   **8.5.137 Get Package UUID response (0xD2)**

4010   The package shall, in the absence of an error, always accept the Get Package UUID command and send  
4011   the response packet shown in Table 259. Currently no command-specific reason code is identified for this  
4012   response.  
4013

4014

Table 259 – Get Package UUID response packet format

	Bits			
Bytes	31..24	23..16	15..08	07..00

16..19	Response Code		Reason Code	
20..35	UUID bytes 1:16, respectively			
36..39	Checksum			
40..45	Pad			

4015 The individual fields within the UUID are stored most-significant byte (MSB) first per the convention  
 4016 described in [RFC4122](#). RFC4122 specifies four different versions of UUID formats and generation  
 4017 algorithms suitable for use for a UUID. These are version 1 (0001b) "time based", and three "name-  
 4018 based" versions: version 3 (0011b) "MD5 hash", version 4 (0100b) "Pseudo-random", and version 5  
 4019 "SHA1 hash". The version 1 format is recommended, however versions 3, 4, or 5 formats are also  
 4020 allowed to be used. See Table 260 for the UUID format version 1.

4021

Table 260 – UUID Format

Field	UUID Byte	MSB

## 4022 8.6 AEN packet formats

4023 This clause defines the formats for the different types of AEN packets. For a list of the AEN types, see  
 4024 Table 18.

### 8.6.1 Link Status Change AEN

The Link Status Change AEN indicates to the Management Controller any changes in the channel's external Ethernet interface link status.

This AEN should be sent if any change occurred in the link status (that is, the actual link mode was changed). The Link Status and OEM Link Status fields reproduce the bit definitions defined in the Get Link Status Response Packet (see Table 52).

Table 261 illustrates the packet format of the Link Status Change AEN.

**Table 261 – Link Status Change AEN packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x00
20..23	Link Status			
24..27	OEM Link Status			
28..31	Checksum			

### 8.6.2 Configuration Required AEN

The Configuration Required AEN indicates to the Management Controller that the channel is transitioning into the Initial State. (This AEN is not sent if the channel enters the Initial State because of a Reset Channel command.)

NOTE: This AEN may not be generated in some situations in which the channel goes into the Initial State. For example, some types of hardware resets may not accommodate generating the AEN.

Table 262 illustrates the packet format of the Configuration Required AEN.

**Table 262 – Configuration Required AEN packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x01
20..23	Checksum			

### 8.6.3 Host Network Controller Driver Status Change AEN

This AEN indicates a change of the Host Network Controller Driver Status. Table 263 illustrates the packet format of the AEN.

Table 263 – Host Network Controller Driver Status Change AEN packet format

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x02
20..23	Host Network Controller Driver Status			
24..27	Checksum			

The Host Network Controller Driver Status field has the format shown in Table 264.

Table 264 – Host Network Controller Driver Status format

Bit Position	Name	Description
0	Host Network Controller Driver Status	0b = The Network Controller driver for the host external network interface associated with this channel is not operational (not running).  1b = The Network Controller driver for the host external network interface associated with this channel is being reported as operational (running).
1..31	Reserved	Reserved

#### 8.6.4 Delayed Response Ready AEN

This AEN indicates the response to a delayed command is ready. Table 265 illustrates the packet format of the AEN.

NOTE: This AEN does not deliver the delayed command response, it must be retrieved separately.

Table 265 – Delayed Response Ready AEN packet format

	Bits			
Bytes	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x03
20..23	Original Command Type	Original Command IID	Padding	
24..27	Checksum			

The Original Command Type includes the Control Packet Type field of the completed command and the Original Command IID includes the IID field of the original command.

#### 8.6.5 InfiniBand Link Status Change AEN

The InfiniBand Link Status Change AEN indicates to the Management Controller any changes in the channel's external InfiniBand interface link status.

This AEN should be sent if any change occurred in the link status (that is, the actual link mode was changed). The Link Status and OEM Link Status fields reproduce the bit definitions defined in the Get IB Link Status Response Packet (see Table 52).

Table 271 illustrates the packet format of the InfiniBand Link Status Change AEN.

**Table 266 – InfiniBand Link Status Change AEN packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x04
20..23	Link Status			
24..27	OEM Link Status			
28..31	Checksum			

### 8.6.6 Fibre Channel Link Status Change AEN

The Fibre Channel Link Status Change AEN indicates to the Management Controller any changes in the channel's external Fibre Channel interface link status including when trunked.

This AEN should be sent if any change occurred in the link status (that is, the actual link mode was changed). The Link Status and OEM Link Status fields reproduce the bit definitions defined in the Get FC Link Status Response Packet (see Table 52).

Table 278 illustrates the packet format of the FC Link Status Change AEN.

**Table 267 – Fibre Channel Link Status Change AEN packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x05
20..23	Link Status			
24..27	OEM Link Status			
28..31	Checksum			

### 8.6.7 Transceiver Event AEN

This indicates to the Management Controller that a change in presence status or a thermal threshold in the SFF-compliant Transceiver attached to the channel has occurred.

Since some SFF cages have multiple TX and RX lanes, it is possible that multiple NC-SI channels are handled by a single transceiver module or copper cable assembly. Only one instance of the Transceiver Event AEN sent to one of the channels involved is required to enable reporting for all such channels. The NC shall send the Transceiver Event AEN on all affected channels if one or more alerts are triggered.

In the case of FC port trunking (bonding), the 1:1 relationship of NC-SI channel to transceiver is lost and multiple transceivers will handle the aggregated traffic. When operating in trunking mode, one enablement of the AEN will cover all transceivers that are members of the trunk. AENs will be generated individually for members in the trunk and use the SFF Cage number field to identify the transceiver generating the AEN.

Table 268 illustrates the packet format of the AEN.

4084

**Table 268 – Transceiver Event AEN packet format**

Bits				
Bytes	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved	Transceiver Presence	SFF Cage Number	AEN Type = 0x06
20..23	Transceiver Event List			
24..27	Reserved			
28..31	Checksum			

**4085 8.6.7.1 SFF Cage Number field**

4086 SFF cage numbers are assigned to SFF cages in the implementation based on the NC-SI channel they  
 4087 are associated with (when not trunked) offset by one. Thus, the SFF cage associated with NC-SI channel  
 4088 0 is #1, channel 1 has cage 2, etc.

**4089 8.6.7.2 Transceiver Event List field**

4090 The Transceiver Event List field has the format shown in Table 269.

4091

**Table 269 – Transceiver Event List format**

Bit Position	Name	Description
0	Low Temp Warning	0b = no alert 1b = The Transceiver's low temperature warning threshold has been exceeded
1	High Temp Warning	0b = no alert 1b = The Transceiver's high temperature warning threshold has been exceeded
2	Low Temp Alarm	0b = no alert 1b = The Transceiver's low temperature alarm threshold has been exceeded
3	High Temp Alarm	0b = no alert 1b = The Transceiver's high temperature alarm threshold has been exceeded
4	Low Voltage Warning	0b = no alert 1b = The Transceiver's low voltage warning threshold has been exceeded
5	High Voltage Warning	0b = no alert 1b = The Transceiver's high voltage warning threshold has been exceeded
6	Low Voltage Alarm	0b = no alert 1b = The Transceiver's low voltage alarm threshold has been exceeded

Bit Position	Name	Description
7	High Voltage Alarm	0b = no alert 1b = The Transceiver's high voltage alarm threshold has been exceeded
15..8	8 x RX Power Levels	0b = no alert 1b = The Transceiver's RX Power alarm threshold has been exceeded. lsb is lane 1 thru msb is lane8
23..16	8 x TX Power Levels	0b = no alert 1b = The Transceiver's TX Power alarm threshold has been exceeded. lsb is lane 1 thru msb is lane8
31..24	8 x TX Bias Levels	0b = no alert 1b = The Transceiver's TX Bias Current alarm threshold has been exceeded. lsb is lane 1 thru msb is lane8

### 4092 8.6.7.3 Transceiver Presence field

4093 Table 270 – Transceiver Presence format

Bit Position	Name	Description
0	Transceiver Presence Change	0b = No change in presence detected 1b = The Transceiver was either removed or inserted. The insertion event reporting shall occur only after the Transceiver has completed its initialization stage
7..1	Reserved	

### 4094 8.6.8 Request Data Transfer AEN

4095 This AEN indicates to the Management Controller that the NC is requesting the MC initiate a transfer of  
 4096 an opaque data package from the NC to the MC. It is sent using an Internal Channel ID value of 0x1F to  
 4097 indicate a package-level operation.

4098 Table 271 illustrates the packet format of the AEN.

4099 **Table 271 – Request Data Transfer AEN packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x07
20..23	Total Length of Transfer (Bytes)			
	Data Handle			
24..27	Checksum			

### 4100 8.6.9 Partition Link Status Change AEN

4101 The Partition Link Status Change AEN indicates to the Management Controller any change in the internal  
 4102 link status of any partition on the channel. This AEN is only valid when the NC supports partitioning and it  
 4103 is enabled.

4104 This AEN should be sent if any change occurred in the internal link status of any enabled partition on the  
 4105 channel.

4106 Table 272 illustrates the packet format of the Partition Link Status Change AEN.

4107 **Table 272 – Partition Link Status Change AEN packet format**

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x08

4109 **Table 273 – Partition Map Field**

Bit	Description
0	0b = Partition 1 on channel link state has not changed 1b = Partition 1 on channel link state has changed
1	0b = Partition 2 on channel link state has not changed 1b = Partition 2 on channel link state has changed
...	...
7	0b = Partition 8 on channel link state has not changed 1b = Partition 8 on channel link state has changed

4110

Table 274 – Partition Link Status

Bit	Description
0	0b = Partition 1 on channel link is down 1b = Partition 1 on channel link is up
1	0b = Partition 2 on channel link is down 1b = Partition 2 on channel link is up
...	...
7	0b = Partition 8 on channel link is down 1b = Partition 8 on channel link is up

4111 **8.6.10 Thermal Shutdown Event AEN**

4112 The Thermal Shutdown Event AEN indicates to the Management Controller that NC device shutdown is  
 4113 imminent due to the defined thermal threshold being reached. It is sent using an Internal Channel ID  
 4114 value of 0x1F to indicate a package-level operation.

4115 Table 275 illustrates the packet format of the Thermal Shutdown Event AEN.

4116 Table 275 – Thermal Shutdown Event AEN packet format

Bytes	Bits			
	31..24	23..16	15..08	07..00
00..15	AEN Header			
16..19	Reserved			AEN Type = 0x09
20..23	Checksum			

4117 **8.6.11 Pending PLDM Request AEN**

4118 The Pending PLDM Request AEN is an RBT-specific AEN used to alert the MC that there is a pending  
 4119 PLDM request for the MC in the NC. This AEN allows for the MC to poll for pending PLDM request on the  
 4120 NC at a lower rate. It is sent using an Internal Channel ID value of 0x1F to indicate a package-level  
 4121 operation.

4122 As a transport-specific AEN, this AEN is enabled using the transport-specific AEN enable command and  
 4123 is controlled by bit 1 in Transport Specific AEN's enable field.

4124 This AEN should be sent if there is a new pending PLDM command that is available in the NC designated  
 4125 to the MC, which was not reported to the MC through **Send NC PLDM Reply Response (0xD7)**. A  
 4126 Pending PLDM Request AEN should not be sent from the time the NC recognizes an incoming **Query**  
 4127 **Pending NC PLDM Request (0x56)** until the NC sends **Send NC PLDM Reply Response (0xD7)** for the  
 4128 PLDM request.

4129

24..45	Pad			

4130 **8.6.12 Pending SPDM Request AEN**

4131 The Pending SPDM Request AEN is an RBT-specific AEN used to alert the MC that there is a pending  
 4132 SPDM command request for the MC in the NC. It is sent using an Internal Channel ID value of 0x1F to  
 4133 indicate a package-level operation.

4134 As a transport-specific AEN, this AEN is enabled using the transport-specific AEN enable command and  
 4135 is controlled by bit 2 in Transport Specific AEN's enable field.

4136 This AEN should be sent if there is a new pending SPDM command that is generated in the NC  
 4137 designated for the MC, which was not reported to the MC through **Send NC PLDM Reply Response**  
 4138 (0xD7). A Pending SPDM Request AEN should not be sent from the time the NC recognizes an incoming  
 4139 **Query Pending NC PLDM Request** (0x56) until the NC sends **Send NC PLDM Reply Response** (0xD7)  
 4140 for the SPDM request.

## 9 Packet-based and opcode timing

Table 278 presents the timing specifications for a variety of packet-to-electrical-buffer interactions, inter-packet timings, and opcode processing requirements. The following timing parameters shall apply to NC-SI over RBT binding defined in this specification.

**Table 278 – NC-SI packet-based and opcode timing parameters**

Name	Symbol	Value	Description
Package Deselect to Hi-Z Interval	T1	200 $\mu$ s, max	Maximum time interval from when a Network Controller completes transmitting the response to a Deselect Package command to when the Network Controller outputs are in the high-impedance state  Measured from the rising edge of the first clock that follows the last bit of the packet to when the output is in the high-impedance state as defined in clause 10
Package Output to Data	T2	2 clocks, min	Minimum time interval after powering up the output drivers before a Network Controller starts transmitting a packet through the NC-SI interface  Measured from the rising edge of the first clock of the packet
Network Controller Power Up Ready Interval	T4	2 s, max	Time interval from when the NC-SI on a Network Controller is powered up to when the Network Controller is able to respond to commands over the NC-SI  Measured from when $V_{ref}$ becomes available
Normal Execution Interval	T5	50 ms, max	Maximum time interval from when a controller receives a command to when it delivers a response to that command, unless otherwise specified  Measured from the rising edge of the first clock following the last bit of the command packet to the rising edge of the clock for the first bit of the response packet
Asynchronous Reset Interval	T6	2 s, max	Interval during which a controller may not recognize or respond to commands or handle Pass-through traffic due to an Asynchronous Reset event. See clause 6.1.8  For a Management Controller, this means that a Network Controller could become unresponsive for up to T6 seconds if an Asynchronous Reset event occurs. This is not an error condition. The Management Controller retry behavior should be designed to accommodate this possibility.
Synchronous Reset Interval	T7	2 s, max	Interval during which a controller may not recognize or respond to commands or handle Pass-through traffic due to a Synchronous Reset event. See clause 6.1.8  Measured from the rising edge of the first clock following the last bit of the Reset Channel response packet
Token Timeout	T8	32,000 REF_CLK min	Number of REF_CLKs before timing out while waiting for a TOKEN to be received

Name	Symbol	Value	Description
Opcode Processing	T9	32 REF_CLK max	Number of REF_CLKs after receiving an opcode on ARB_IN to decode the opcode and generate the next opcode on ARB_OUT  Measured from the falling edge of the last bit of the opcode received on ARB_IN to the rising edge of the next opcode on ARB_OUT
Opcode Bypass Delay	T10	32 REF_CLK max	Number of REF_CLK delays between a bit received on ARB_IN and the corresponding bit passed on to ARB_OUT while in Bypass Mode  Measured from the falling edge of the last bit of the opcode received on ARB_IN to the rising edge of the next opcode on ARB_OUT
TOKEN to RXD	T11	T2 min, 32 REF_CLK max	Number of REF_CLKs after receiving TOKEN to when packet data is driven onto the RXD lines  Measured from the falling edge of the last bit of the opcode received on ARB_IN to the rising edge of the first clock of the next packet on RXD
Max XOFF Renewal Interval	T12	50,331,648 REF_CLK max	Maximum time period (3 XOFF Frame timer cycles) during which a channel within a package is allowed to request and renew a single XOFF condition after requesting the initial XOFF
IPG to TOKEN Opcode Overlap	T13	6 REF_CLK max	Maximum number of REF_CLKs that the beginning of TOKEN transmission can precede the end of the Inter Packet Gap. For more information, see clause 7.3.8.
Delayed Execution Interval	T14	4 s, max	Maximum time interval from when a controller receives a command to when it delivers a response to that command, including all responses with "Delayed Response" code  Measured from the rising edge of the first clock following the last bit of the command packet to the rising edge of the clock for "Delayed Response Ready" AEN if enabled or to the moment the NC is internally ready with a response for a polling command.
NOTE: If hardware arbitration is in effect, the hardware arbitration output buffer enable/disable timing specifications take precedence.			

4149  
4150  
4151

## 10 RBT Electrical specification

This clause provides background information about the NC-SI RBT specification, describes the RBT topology, and defines the electrical, timing, signal behavior, and power-up characteristics for the RBT physical interface.

### 10.1 Topologies

The electrical specification defines the RBT electrical characteristics for one management processor and one to four Network Controller packages in a bussed “multi-drop” arrangement. The actual number of devices that can be supported may differ based on the trace characteristics and routing used to interconnect devices in an implementation.

Figure 16 shows an example topology.

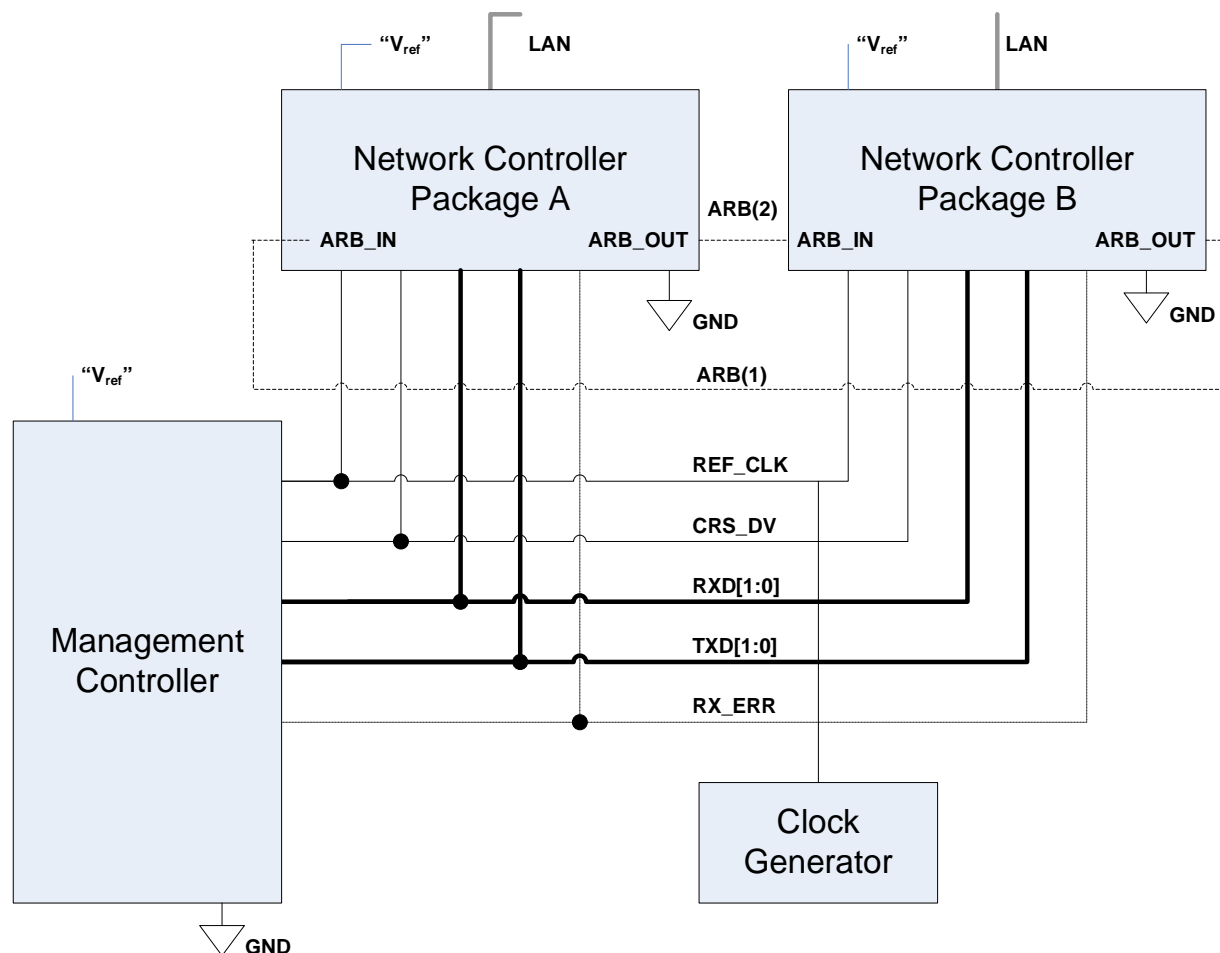

Figure 16 – Example NC-SI RBT signal interconnect topology

## 4164 **10.2 Electrical and signal characteristics and requirements**

4165 This clause defines the electrical, timing, signal behavior, and power-up characteristics for the NC-SI RBT  
4166 physical interface.

### 4167 **10.2.1 Companion specifications**

4168 Implementations of the physical interface and signaling for RBT shall meet the specifications in [RMII](#) and  
4169 [IEEE 802.3](#), except where those requirements differ or are extended with specifications provided in this  
4170 document, in which case the specifications in this document shall take precedence.

### 4171 **10.2.2 Full-duplex operation**

4172 RBT is specified only for full-duplex operation. Half-duplex operation is not covered by this specification.

### 4173 **10.2.3 Signals**

4174 Table 279 lists the signals that make up the RBT physical interface.

4175 Unless otherwise specified, the high level of a RBT signal corresponds to its asserted state, and the low  
4176 level represents the de-asserted state. For data bits, the high level represents a binary '1' and the low  
4177 level a binary '0'.

4178

4179

Table 279 – Physical RBT signals

Signal Name	Direction (with respect to the Network Controller)	Direction (with respect to the Management Controller MAC)	Use	Mandatory or Optional
REF_CLK <sup>[a]</sup>	Input	Input	Clock reference for receive, transmit, and control interface	M
CRS_DV <sup>[b]</sup>	Output	Input	Carrier Sense/Receive Data Valid	M
RXD[1:0]	Output	Input	Receive data	M
TX_EN	Input	Output	Transmit enable	M
TXD[1:0]	Input	Output	Transmit data	M
RX_ER	Output	Input	Receive error	O
ARB_IN	Input <sup>[c]</sup>	N/A	Network Controller hardware arbitration Input	O <sup>[c]</sup>
ARB_OUT	Output <sup>[c]</sup>	N/A	Network Controller hardware arbitration Output	O <sup>[c]</sup>
<p>A device can provide an additional option to allow it to be configured as the source of REF_CLK, in which case the device is not required to provide a separate REF_CLK input line, but it can use REF_CLK input pin as an output. The selected configuration shall be in effect at NC power up and remain in effect while the NC is powered up.</p> <p>In the <a href="#">RMII Specification</a>, the MII Carrier Sense signal, CRS, was combined with RX_DV to form the CRS_DV signal. When RBT is using its specified full-duplex operation, the CRS aspect of the signal is not required; therefore, the signal shall provide only the functionality of RX_DV as defined in <a href="#">IEEE 802.3</a>. (This is equivalent to the CRS_DV signal states in <a href="#">RMII Specification</a> when a carrier is constantly present.) The Carrier Sense aspect of the CRS_DV signal is not typically applicable to RBT because it does not typically detect an actual carrier (unlike an actual PHY). However, the Network Controller should emulate a carrier-present status on CRS_DV per <a href="#">IEEE 802.3</a> in order to support Management Controller MACs that may require a carrier-present status for operation.</p> <p>If hardware arbitration is implemented, the Network Controller package shall provide both ARB_IN and ARB_OUT connections. In some implementations, ARB_IN may be required to be tied to a logic high or low level if it is not used.</p>				

#### 4180 10.2.4 High-impedance control

4181 Shared RBT operation requires Network Controller devices to be able to set their outputs (RXD[1:0],  
 4182 CRS\_DV, and, if implemented, RX\_ER) into a high-impedance state either upon receipt of a command  
 4183 being received, or, if hardware-based arbitration is enabled as a result of hardware-based arbitration. A  
 4184 pull-down resistor should be provided on high impedance signals to prevent them from floating when not  
 4185 driven.

4186 Network Controllers shall leave their RBT outputs in the high-impedance state on interface power up and  
 4187 shall not drive them until the package is selected. For additional information about Network Controller  
 4188 packages, see 8.5.5.

4189 For RBT output signals in this specification, unless otherwise specified, the high-impedance state is  
 4190 defined as the state in which the signal leakage meets the  $I_z$  specification provided in 10.2.5.

#### 4191 10.2.5 Hardware Implementations

4192 A variety of shared RBT hardware implementations are possible, in such cases the designer must take  
 4193 care to ensure the HW arbitration loop is maintained when used, even if some RBT devices are not  
 4194 present. Pull resistors are recommended to be placed on the system board side of any connector for add-  
 4195 in RBT cards so that a proper resistance for the high impedance signals can be maintained.

## 10.2.6 DC characteristics

This clause defines the DC characteristics of the RBT physical interface.

### 10.2.6.1 Signal levels

CMOS 3.3 V signal levels are used for this specification.

The following characteristics apply to DC signals:

- Unless otherwise specified, DC signal levels and  $V_{ref}$  are measured relative to Ground (GND) at the respective device providing the interface, as shown in Figure 17.
- Input specifications refer to the signals that a device shall accept for its input signals, as measured at the device.
- Output specifications refer to signal specifications that a device shall emit for its output signals, as measured at the device.

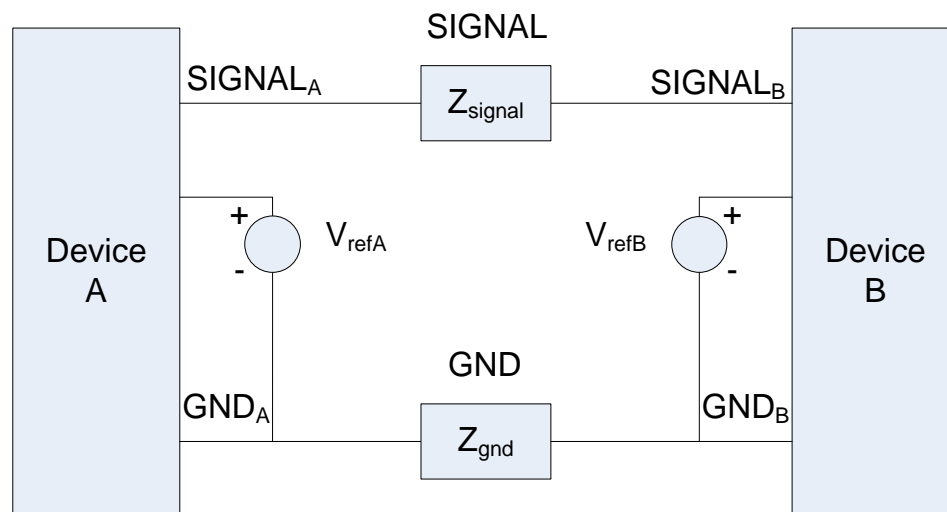

Figure 17 – DC measurements

4209 Table 280 provides DC specifications.

4210 **Table 280 – DC specifications**

Parameter	Symbol	Conditions	Minimum	Typical	Maximum	Units
IO reference voltage	$V_{ref}^{[a]}$		3.0	3.3	3.6	V
Signal voltage range	$V_{abs}$		-0.300		3.765	V
Input low voltage	$V_{il}$				0.8	V
Input high voltage	$V_{ih}$		2.0			V
Input high current	$I_{ih}$	$V_{in} = V_{ref} = V_{ref,max}$	0		200	$\mu A$
Input low current	$I_{il}$	$V_{in} = 0 V$	-20		0	$\mu A$
Output low voltage	$V_{ol}$	$I_{ol} = 4 mA, V_{ref} = min$	0		400	mV
Output high voltage	$V_{oh}$	$I_{oh} = -4 mA, V_{ref} = min$	2.4		$V_{ref}$	V
Clock midpoint reference level	$V_{ckm}$				1.4	V
Leakage current for output signals in high-impedance state	$I_z$	$0 \leq V_{in} \leq V_{ref}$ at $V_{ref} = V_{ref,max}$	-20		20	$\mu A$

$V_{ref}$  = Bus high reference level (typically the NC-SI logic supply voltage). This parameter replaces the term supply voltage because actual devices may have internal mechanisms that determine the operating reference for RBT that are different from the devices' overall power supply inputs.

$V_{ref}$  is a reference point that is used for measuring parameters (such as overshoot and undershoot) and for determining limits on signal levels that are generated by a device. To facilitate system implementations, a device shall provide a mechanism (for example, a power supply pin, internal programmable reference, or reference level pin) to allow  $V_{ref}$  to be set to within 20 mV of any point in the specified  $V_{ref}$  range. This approach enables a system integrator to establish an interoperable  $V_{ref}$  level for devices on RBT.

## 4211 10.2.7 AC characteristics

4212 This clause defines the AC characteristics of the RBT physical interface.

### 4213 10.2.7.1 Rise and fall time measurement

4214 Rise and fall time are measured between points that cross 10% and 90% of  $V_{ref}$  (see Table 280). The  
4215 middle points (50% of  $V_{ref}$ ) are marked as  $V_{ckm}$  and  $V_m$  for clock and data, respectively.

### 4216 10.2.7.2 REF\_CLK measuring points

4217 In Figure 18, REF\_CLK duty cycle measurements are made from  $V_{ckm}$  to  $V_{ckm}$ . Clock skew  $T_{skew}$  is  
4218 measured from  $V_{ckm}$  to  $V_{ckm}$  of two RBT devices and represents the maximum clock skew between any  
4219 two devices in the system.

### 4220 10.2.7.3 Data, control, and status signal measuring points

4221 In Figure 18, all timing measurements are made between  $V_{ckm}$  and  $V_m$ .  $T_{co}$  is measured with a capacitive  
4222 load between 10 pF and 50 pF. Propagation delay  $T_{prop}$  is measured from  $V_m$  on the transmitter to  $V_m$  on  
4223 the receiver.

Figure 18 – AC measurements

Table 281 provides AC specifications.

Table 281 – AC specifications

Parameter	Symbol	Minimum	Typical	Maximum	Units
REF_CLK Frequency			50	50+100 ppm	MHz
REF_CLK Duty Cycle		35		65	%
Clock-to-out <sup>[a]</sup> (10 pF ≤ C <sub>load</sub> ≤ 50 pF)	T <sub>co</sub>	2.5		12.5	ns
Skew between clocks	T <sub>skew</sub>			1.5	ns
TXD[1:0], TX_EN, RXD[1:0], CRS_DV, RX_ER, and ARB_IN data setup to REF_CLK rising edge	T <sub>su</sub>	3			ns
TXD[1:0], TX_EN, RXD[1:0], CRS_DV, RX_ER, and ARB_OUT data hold from REF_CLK rising edge	T <sub>hd</sub>	1			ns
Signal Rise/Fall Time	T <sub>r</sub> /T <sub>f</sub>	0.5		6	ns
REF_CLK Rise/Fall Time	T <sub>ckr</sub> /T <sub>ckf</sub>	0.5		3.5	ns
Interface Power-Up High-Impedance Interval	T <sub>pwz</sub>	2			μs
Power Up Transient Interval (recommendation)	T <sub>pwrt</sub>			100	ns
Power Up Transient Level (recommendation)	V <sub>pwrt</sub>	-200		200	mV
REF_CLK Startup Interval	T <sub>clkstrt</sub>			100	ms

This timing relates to the output pins, while T<sub>su</sub> and T<sub>hd</sub> relate to timing at the input pins.

#### 10.2.7.4 Timing calculation (informative)

##### 10.2.7.4.1 Setup time calculation

$$T_{su} \leq T_{clk} - (T_{skew} + T_{co} + T_{prop})$$

**10.2.7.4.2 Hold time calculation**

$$T_{hd} \leq T_{co} - T_{skew} + T_{prop}$$

**10.2.7.5 Overshoot specification**

Devices shall accept signal overshoot within the ranges specified in Figure 19, measured at the device, without malfunctioning.

**Figure 19 – Overshoot measurement**

The signal may overshoot up to the specified  $V_{max}$  for the first 3 ns following the transition above  $V_{ih}$ . Following that interval is an exponential decay envelope equal to the following:

$$V_{ref} + V_{os} * e^{[-K * (t - 3 \text{ ns}) / T_d]}$$

Where, for  $t = 3$  to 10 ns:

$t = 0$  corresponds to the leading crossing of  $V_{ih}$ , going high.

$V_{ref}$  is the bus high reference voltage (see 10.2.5).

$V_{abs,max}$  is the maximum allowed signal voltage level (see 10.2.5).

$$V_{os} = V_{max} - V_{ref}$$

$$K = \ln(25 \text{ mV} / V_{os})$$

$$T_d = 7 \text{ ns}$$

For  $t > 10$  ns, the  $V_{ref} + 25 \text{ mV}$  limit holds flat until the conclusion of  $T_{high}$ .

**10.2.7.6 Undershoot specification**

Devices are required to accept signal undershoot within the ranges specified in Figure 20, measured at the device, without malfunctioning.

**Figure 20 – Undershoot measurement**

The signal is allowed to undershoot up to the specified  $V_{\text{abs,min}}$  for the first 3 ns following the transition above  $V_{\text{il}}$ . Following that interval is an exponential envelope equal to the following:

$$* ([t - 3 \text{ ns}] / T_d)$$

Where, for  $t = 3$  to  $10$  ns:

$t = 0$  corresponds to the leading crossing of  $V_{\text{il}}$ , going low.

$V_{\text{abs,min}}$  is the minimum allowed signal voltage level (see 10.2.5).

$$K = \ln(25 \text{ mV} / V_{\text{os}})$$

$$T_d = 7 \text{ ns}$$

For  $t > 7$  ns, the GND – 25 mV limit holds flat until the conclusion of  $T_{\text{low}}$ .

## 10.2.8 Interface power-up

To prevent signals from back-powering unpowered devices, it is necessary to specify a time interval during which signals are not to be driven until devices sharing the interface have had time to power up. To facilitate system implementation, the start of this interval shall be synchronized by an external signal across devices.

### 10.2.8.1 Power-up control mechanisms

The device that provides the interface shall provide one or more of the following mechanisms to enable the system integrator to synchronize interface power-up among devices on the interface:

- **Device power supply pin**

The device has a power supply pin that the system integrator can use to control power-up of the interface. The device shall hold its outputs in a high-impedance state (current  $< I_z$ ) for at least  $T_{\text{pwrz}}$  seconds after the power supply has initially reached its operating level (where the power supply operating level is specified by the device manufacturer).

- **Device reset pin or another similar signal**

The device has a reset pin or other signal that the system integrator can use to control the power-up of the interface. This signal shall be able to be driven asserted during interface power-up and de-asserted afterward. The device shall hold its outputs in a high-impedance state (current <  $I_z$ ) for at least  $T_{pwrz}$  seconds after the signal has been de-asserted, other than as described in clause 10.2.8.2. It is highly recommended that a single signal be used; however, an implementation is allowed to use a combination of signals if required. Logic levels for the signals are as specified by the device manufacturer.

- **REF\_CLK detection**

The device can elect to detect the presence of an active REF\_CLK and use that for determining whether NC-SI power up has occurred. It is recommended that the device should count at least 100 clocks and continue to hold its outputs in a high-impedance state (current <  $I_z$ ) for at least  $T_{pwrz}$  seconds more (Informational: 100 clocks at 50 MHz is 2 us).

### 10.2.8.2 Power-up transients

It is possible that a device may briefly drive its outputs while the interface or device is first receiving power, due to ramping of the power supply and design of its I/O buffers. It is recommended that devices be designed so that such transients, if present, are less than  $V_{pwrz}$  and last for no more than  $T_{pwrz}$ .

### 10.2.9 REF\_CLK startup

REF\_CLK shall start up, run, and meet all associated AC and DC specifications within  $T_{clkstrt}$  seconds of interface power up.

## 10.3 RBT Implementation guidance

This specification does not define implementation requirements due to the wide variation in architectures, devices and materials used. Following good engineering practices are a key part of a successful NC-SI RBT implementation:

- Care must be taken in placement and layout
- Do a complete signal integrity analysis including determining what, if any, termination is required
- Minimize stubs
- Have uniform clock trace lengths
- Minimize noise on high-impedance signals

## ANNEX A (normative)

### Extending the model

4310 This annex explains how the model can be extended to include vendor-specific content.

#### 4311 **Commands extension**

4312 A Network Controller vendor can implement extensions and expose them using OEM commands, as  
4313 described in clause 8.5.124.

#### 4314 **Design considerations**

4315 This clause describes certain design considerations for vendors of Management Controllers.

#### 4316 **PHY support**

4317 Although not a requirement of this specification, a Management Controller vendor can design the RBT  
4318 interface in such a manner that it could also be configured for use with a conventional RMII PHY. This  
4319 would enable the vendor's controller to also be used in applications where a direct, non-shared network  
4320 connection is available or preferred for manageability.

#### 4321 **Multiple Management Controllers support**

4322 Currently, there is no requirement for Management Controllers to be able to put their TXD output lines  
4323 and other output lines into a high-impedance state, because the present definition assumes only one  
4324 Management Controller on the bus. However, component vendors can provide such control capabilities in  
4325 their devices to support possible future system topologies where more than one Management Controller  
4326 shares the bus to enable functions such as Management Controller fail-over or to enable topologies  
4327 where more than one Management Controller can participate in NC-SI communications on the bus. If a  
4328 vendor elects to make such provision, it is recommended that the TXD line and the remaining output lines  
4329 be independently and dynamically switched between a high-impedance state and re-enabled under  
4330 firmware control.

4331

## ANNEX B (informative)

### Relationship to RMI Specification

#### Differences with the *RMI Specification*

The following list presents key differences and clarifications between the *NC-SI Specification* and sections in the [RMI Specification](#). (Section numbers refer to the [RMI Specification](#).)

- General: Where specifications from [IEEE 802.3](#) apply, this specification uses the version specified in clause 2 (Normative references), rather than the earlier IEEE 802.3u version that is referenced by [RMI](#).
- Section 1.0:
  - The *NC-SI Specification* requires 100 Mbps support, but it does not specify a required minimum. (10 Mbps support is not required by NC-SI.)
  - Item 4. (Signals may or may not be considered to be TTL. NC-SI is not 5-V tolerant.)
- Section 2.0:
  - Comment: NC-SI chip-to-chip includes considerations for multi-drop and allows for non-PCB implementations and connectors (that is, not strictly point-to-point).
- Section 3.0:
  - Note/Advisory: The NC-SI clock is provided externally. An implementation can have REF\_CLK provided by one of the devices on the bus or by a separate device.
- Section 5.0:
  - For NC-SI, the term *PHY* is replaced by *Network Controller*.
- Table 1:
  - The information in Table 1 in the [RMI Specification](#) is superseded by tables in this specification.
- Section 5.1, paragraph 2:
  - The *NC-SI Specification* allows 100 ppm. This supersedes the [RMI Specification](#), which allows 50 ppm.
- Section 5.1, paragraph 3:
  - The NC-SI inherits the same requirements. The NC-SI MTU is required only to support Ethernet MTU with VLAN, as defined in the [IEEE 802.3](#) version listed in clause 2
- Section 5.1 paragraph 4:
  - The [RMI Specification](#) states: "During a false carrier event, CRS\_DV shall remain asserted for the duration of carrier activity." This statement is not applicable to full-duplex operation of the NC-SI. CRS\_DV from the Network Controller is used only as a data valid (DV) signal. Because the Carrier Sense aspect of CRS\_DV is not used for full-duplex operation of the NC-SI, the Network Controller would not generate false carrier events for the NC-SI. However, it is recommended that the MAC in the Management Controller be able to correctly detect and handle these patterns if they occur, as this would be part of enabling the Management Controller MAC to also be able to work with an RMI PHY.

- 4372 • Section 5.2:
- 4373 – The NC-SI does not specify a 10 Mbps mode. The Carrier Sense aspect of CRS\_DV is not
- 4374 used for full-duplex operation of NC-SI.
- 4375 • Section 5.3.1:
- 4376 – While the NC-SI does not specify Carrier Sense usage of CRS\_DV, it is recommended that
- 4377 a Management Controller allow for CRS\_DV toggling, in which CRS\_DV toggles at 1/2
- 4378 clock frequency, and that Management Controller MACs tolerate this and realign bit
- 4379 boundaries correctly in order to be able to work with an RMII PHY also.
- 4380 • Section 5.3.2:
- 4381 – There is no 10 Mbps mode specified for the NC-SI RBT interface.
- 4382 • Section 5.3.3:
- 4383 – Generally, there is no expectation that the Network Controller will generate these error
- 4384 conditions for the NC-SI; however, the MAC in the Management Controller should be able
- 4385 to correctly detect and handle these patterns if they occur.
- 4386 • Section 5.3.3:
- 4387 – The NC-SI does not specify or require support for RMII Registers.
- 4388 • Section 5.5.2:
- 4389 – Ignore (N/A) text regarding 10 Mbps mode. RBT does not specify or require interface
- 4390 operation in 10 Mbps mode.
- 4391 • Section 5.6:
- 4392 – The Network Controller will not generate collision patterns for the specified full-duplex
- 4393 operation of the NC-SI; however, the MAC in the Management Controller should be able to
- 4394 detect and handle these patterns if they occur in order to be able to work with an RMII PHY
- 4395 also.
- 4396 • Section 5.7:
- 4397 – NC-SI RBT uses the [IEEE 802.3](#) version listed in clause 2 instead of 802.3u as a
- 4398 reference.
- 4399 • Section 5.8:
- 4400 – Loopback operation is not specified for the NC-SI RBT interface.
- 4401 • Section 7.0:
- 4402 – The NC-SI RBT electrical specifications (clause 10) take precedence. (For example,
- 4403 section 7.4.1 in the [RMII Specification](#) for capacitance is superseded by *NC-SI*
- 4404 *Specification* 25 pF and 50 pF target specifications.)
- 4405 • Section 8.0:
- 4406 – NC-SI RBT uses the [IEEE 802.3](#) version listed in clause 2 (Normative references) as a
- 4407 reference, instead of 802.3u.
