DMTF is a not-for-profit association of industry members dedicated to promoting enterprise and systems management and interoperability. Members and non-members may reproduce DMTF specifications and documents, provided that correct attribution is given. As DMTF specifications may be revised from time to time, the particular version and release date should always be noted.

17 Implementation of certain elements of this standard or proposed standard may be subject to third party18 patent rights, including provisional patent rights (herein "patent rights"). DMTF makes no representations

19 to users of the standard as to the existence of such rights, and is not responsible to recognize, disclose,

or identify any or all such third party patent right, owners or claimants, nor for any incomplete or
 inaccurate identification or disclosure of such rights, owners or claimants. DMTF shall have no liability to

any party, in any manner or circumstance, under any legal theory whatsoever, for failure to recognize,

disclose, or identify any such third party patent rights, or for such party's reliance on the standard or

incorporation thereof in its product, protocols or testing procedures. DMTF shall have no liability to any

25 party implementing such standard, whether such implementation is foreseeable or not, nor to any patent

26 owner or claimant, and shall have no liability or responsibility for costs or losses incurred if a standard is

27 withdrawn or modified after publication, and shall be indemnified and held harmless by any party

implementing the standard from any and all claims of infringement by a patent owner for such

29 implementations.

30 For information about patents held by third-parties which have notified the DMTF that, in their opinion,

31 such patent may relate to or impact implementations of DMTF standards, visit

305

Introduction

In out-of-band management environments, the interface between the out-of-band Management Controller
 and the Network Controller is critical. This interface is responsible for supporting communication between
 the Management Controller and external management applications. Currently there are multiple such
 proprietary interfaces in the industry, leading to inconsistencies in implementation of out-of-band
 management.

The goal of this specification is to define an interoperable sideband communication interface standard to enable the exchange of management data between the Management Controller and Network Controller. The Sideband Interface is intended to provide network access for the Management Controller, and the

314 Management Controller is expected to perform all the required network functions.

315 This specification defines the protocol and commands necessary for the operation of the sideband

communication interface. This specification also defines physical and electrical characteristics of a
 sideband binding interface that is a variant of RMII targeted specifically for sideband communication

318 traffic.

319 The specification is primarily intended for architects and engineers involved in the development of

network interface components and Management Controllers that will be used in providing out-of-band
 management.

323 **1 Scope**

This specification defines the functionality and behavior of the Sideband Interface responsible for connecting the Network Controller to the Management Controller. It also outlines the behavioral model of the network traffic destined for the Management Controller from the Network Controller.

- 327 This specification defines the following two aspects of the Network Controller Sideband Interface (NC-SI):
- behavior of the interface, which include its operational states as well as the states of the associated components
- the payloads and commands of the communication protocol supported over the interface
- The scope of this specification is limited to addressing only a single Management Controller communicating with one or more Network Controllers.
- This specification also defines the following aspects of a 3.3V RMII Based Transport (RBT) based physical medium:
- transport binding for NC-SI over RBT
- electrical and timing requirements for the RBT
- an optional hardware arbitration mechanism for RBT

338 Only the topics that may affect the behavior of the Network Controller or Management Controller, as it 339 pertains to the Sideband Interface operations, are discussed in this specification.

370 3 Terms and definitions

371 For the purposes of this document, the following terms and definitions apply.

372 3.1 Requirement term definitions

- 373 This clause defines key phrases and words that denote requirement levels in this specification.
- 374 **3.1.1**

375 conditional

- 376 indicates that an item is required under specified conditions
- 377 **3.1.2**
- 378 deprecated
- indicates that an element or profile behavior has been outdated by newer constructs
- 380 **3.1.3**
- 381 mandatory
- indicates that an item is required under all conditions
- 383 **3.1.4**
- 384 **may**
- indicates that an item is truly optional
- NOTE An implementation that does not include a particular option shall be prepared to interoperate with another
 implementation that does include the option, although perhaps with reduced functionality. An implementation
 that does include a particular option shall be prepared to interoperate with another implementation that does
 include the option (except for the feature that the option provides).
- 390 **3.1.5**
- 391 may not
- 392 indicates flexibility of choice with no implied preference

424 425	acceptable or even useful, but the full implications should be understood and carefully weighed before implementing any behavior described with this label
421 422 423	3.1.14 should not indicates that valid reasons may exist in particular circumstances when the particular behavior is
419 420	indicates that valid reasons may exist in particular circumstances to ignore a particular item, but the full implications should be understood and carefully weighed before choosing a different course
417 418	3.1.13 should
414 415 416	3.1.12 shall not indicates that the item is an absolute prohibition of the specification
411 412 413	3.1.11 shall indicates that the item is an absolute requirement of the specification
408 409 410	3.1.10 required indicates that the item is an absolute requirement of the specification
404 405 406 407	3.1.9recommendedindicates that valid reasons may exist in particular circumstances to ignore a particular item, but the full implications should be understood and carefully weighed before choosing a different course
401 402 403	3.1.8 optional indicates that an item is not mandatory, conditional, or prohibited
398 399 400	3.1.7obsoleteindicates that an item was defined in prior specifications but has been removed from this specification
393 394 395 396 397	3.1.6 not recommended indicates that valid reasons may exist in particular circumstances when the particular behavior is acceptable or even useful, but the full implications should be understood and carefully weighed before implementing any behavior described with this label

- 427 For the purposes of this document, the following terms and definitions apply.
- 428 3.2.1
- 429 Frame
- 430 a data packet of fixed or variable length that has been encoded for digital transmission over a node-to-
- 431 node link
- Frame is used in references to IEEE 802.3 Frames. Packet is used in all other references. 432

433	3.2.2 Declari
434 435	Packet a formatted block of information carried by a computer network
436	<i>Frame</i> is used in references to IEEE 802.3 Frames. <i>Packet</i> is used in all other references.
437	3.2.3
437 438	S.Z.S External Network Interface
439 440	the interface of the Network Controller that provides connectivity to the external network infrastructure; also known as <i>port</i>
441 442	3.2.4 Internal Host Interface
443 444	the interface of the Network Controller that provides connectivity to the host operating system running on the platform
445 446	3.2.5 Management Controller
447 448 449	an intelligent entity composed of hardware/firmware/software that resides within a platform and is responsible for some or all of the management functions associated with the platform; also known as BMC and Service Processor
450 451	3.2.6 Network Controller
452 453	the component within a system that is responsible for providing connectivity to an external Ethernet network
454	3.2.7
455	Remote Media
456 457	a manageability feature that enables remote media devices to appear as if they are attached locally to the host
458	3.2.8
459 460	Network Controller Sideband Interface NC-SI
461 462	the interface of the Network Controller that provides network connectivity to a Management Controller; also shown as <i>Sideband Interface</i> or <i>NC-SI</i> as appropriate in the context
463 464	3.2.9 Integrated Controller
465 466 467	a Network Controller device that supports two or more channels for the NC-SI that share a common NC-SI physical interface (for example, a Network Controller that has two or more physical network ports and a single NC-SI bus connection)
468	3.2.10
469	Multi-drop
470 471 472	refers to the situation in which multiple physical communication devices share an electrically common bus and a single device acts as the master of the bus and communicates with multiple "slave" or "target" devices

- 473 Related to NC-SI, a Management Controller serves the role of the master, and the Network Controllers
- 474 are the target devices.

475 **3.2.11**

476 **Point-to-Point**

- 477 refers to the situation in which only a single Management Controller and single Network Controller
- 478 package are used on the bus in a master/slave relationship, where the Management Controller is the 479 master

480 **3.2.12**

481 Channel

- the control logic and data paths that support NC-SI Pass-through operations through a single networkinterface (port)
- A Network Controller that has multiple network interface ports can support an equivalent number of NC-SI
 channels.

486 3.2.13

487 Package

- one or more NC-SI channels in a Network Controller that share a common set of electrical buffers and
 common electrical buffer controls for the NC-SI bus
- Typically, a single, logical NC-SI package exists for a single physical Network Controller package (chip or module). However, this specification allows a single physical chip or module to hold multiple NC-SI logical
- 492 packages.

493 **3.2.14**

494 Control traffic

495 Control Messages

496 command, response, and asynchronous event notification packets transmitted between the Management
 497 Controller and Network Controllers for the purpose of managing the NC-SI

498 **3.2.15**

499 Command

- 500 Control Message sent by the Management Controller to the Network Controller to request the Network
- 501 Controller to perform an action, and/or return data

502 **3.2.16**

503 Response

- 504 Control Message sent by the Network Controller to the Management Controller as a positive
- acknowledgement of a command received from the Management Controller, and to provide the execution
- 506 outcome of the command, as well as to return any required data

507 **3.2.17**

508 Asynchronous Event Notification

- 509 Control Message sent by the Network Controller to the Management Controller as an explicit notification
- 510 of the occurrence of an event of interest to the Management Controller
- 511 **3.2.18**

512 Pass-through traffic

513 Pass-through packets

- 514 network packets passed between the external network and the Management Controller through the
- 515 Network Controller

- 516 **3.2.19**
- 517 **RBT**

518 **RMII Based Transport**

519 Electrical and timing specification for a 3.3V physical medium that is derived from <u>RMII.</u>

520 3.3 Numbers and number bases

Hexadecimal numbers are written with a "0x" prefix (for example, 0xFFF and 0x80). Binary numbers are
written with a lowercase "b" suffix (for example, 1001b and 10b). Hexadecimal and binary numbers are
formatted in the Courier New font.

524 3.4 Reserved fields

525 Unless otherwise specified, reserved fields are reserved for future use and should be written as zeros and 526 ignored when read.

527 **4** Acronyms and abbreviations

- 528 The following symbols and abbreviations are used in this document.
- 529
 4.1

 530

593 **5 NC-SI overview**

594 With the increasing emphasis on out-of-band manageability and functionality, such as Remote Media 595 (R-Media) and Remote Keyboard-Video-Mouse (R-KVM), the need for defining an industry standard 596 Network Controller Sideband Interface (NC-SI) has become clear. This specification enables a common 597 interface definition between different Management Controller and Network Controller vendors. This 598 specification addresses not only the electrical and protocol specifications, but also the system-level 599 behaviors for the Network Controller and the Management Controller related to the NC-SI.

The NC-SI is defined as the interface (protocol, messages, and medium) between a Management
 Controller and one or multiple Network Controllers. This interface, referred to as a Sideband Interface in
 Figure 1, is responsible for providing external network connectivity for the Management Controller while
 also allowing the external network interface to be shared with traffic to and from the host.

The specification of how the NC-SI protocol and messages are implemented over a particular physical medium is referred to as a transport binding. This document, DSP0222, includes the definition of the transport binding, electrical, framing, and timing specifications for a physical interface called RBT (RMII based Transport). Electrically, RBT, as described in clause 10, is similar to the Reduced Media Independent InterfaceTM (RMII) – hence the name. Transport bindings for NC-SI over other media and transport protocols are defined through external transport binding specifications, such as <u>DSP0261</u>, the *NC-SI over MCTP Transport Binding Specification*.

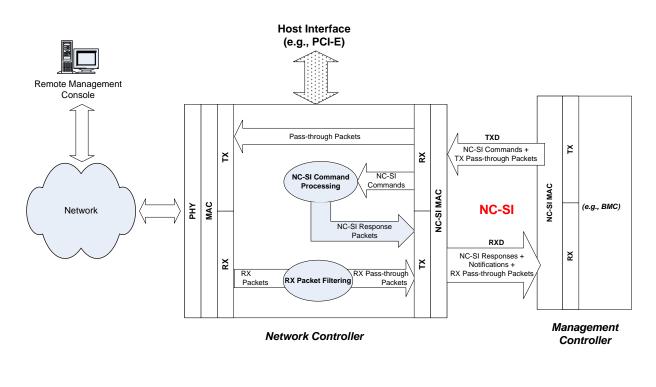

611

612

- 613 NC-SI traffic flow is illustrated in Figure 2. Two classes of packet data can be delivered over the Sideband 614 Interface:
- 615 "Pass-through" packets that are transferred between the Management Controller and the
 616 external network
- 617 "Control" packets that are transferred between the Management Controller and Network
 618 Controllers for control or configuration functionality

620

619

Figure 2 – NC-SI traffic flow diagram

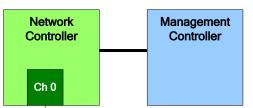

The NC-SI is intended to operate independently from the in-band activities of the Network Controller. As such, the Sideband Interface is not specified to be accessible through the host interface of the Network Controller. From the external world, this interface should behave and operate like a standard Ethernet Interface.

625 **5.1 Defined topologies**

The topologies supported under this specification apply to the case in which a single Management
 Controller is actively communicating with one or more Network Controllers on the NC-SI. The electrical
 specification is targeted to directly support up to four physical Network Controller packages. The protocol
 specification allows up to eight Network Controller packages, with up to 31 channels per package.

- Figure 3 illustrates some examples of Network Controller configurations supported by the NC-SI in the current release:
- Configuration 1 shows a Management Controller connecting to a single Network Controller with a single external network connection.
- Configuration 2 shows a Management Controller connecting to a Network Controller package that supports two NC-SI channels connections.
- 636
 Configuration 3 shows a Management Controller connecting to four discrete Network
 637
 Controllers.

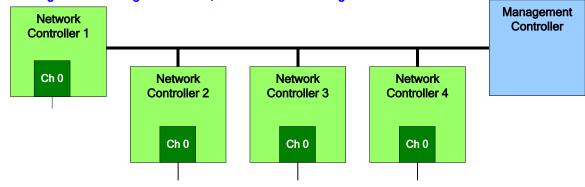

Configuration 1: Single Channel, Single Package

Configuration 2: Integrated Dual Channel, Single Package

Network Controller		 Management Controller

Configuration 3: Single Channels, Four Discrete Packages

638

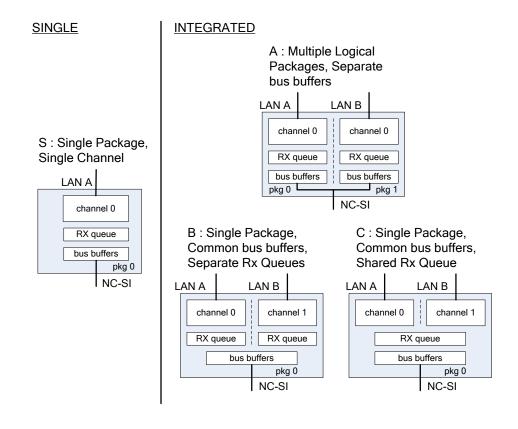

639

Figure 3 – Example topologies supported by the NC-SI

640 **5.2 Single and integrated Network Controller implementations**

This clause illustrates the general relationship between channels, packages, receive buffers, and busbuffers for different controller implementations.

- An integrated controller is a Network Controller that connects to the NC-SI and provides NC-SI support for
- two or more network connections. A single controller is a controller that supports only a single NC-SIchannel.
- 646 For the NC-SI Specification, an integrated controller can be logically implemented in one of three basic
- 647 ways, as illustrated in Figure 4. Although only two channels are shown in the illustration, an integrated
- 648 controller implementation can provide more than two channels. The example channel and package
- 649 numbers (for example, channel 0, pkg 0) refer to the Internal Channel and Package ID subfields of the 650 Channel ID. For more information, see 6.2.9
- 650 Channel ID. For more information, see 6.2.9.

651

652

Figure 4 – Network Controller integration options

Packages that include multiple channels are required to handle internal arbitration between those
 channels and the NC-SI. The mechanism by which this occurs is vendor specific and not specified in this
 document. This internal arbitration is always active by default. No NC-SI commands are defined for
 enabling or disabling internal arbitration between channels.

657 The following classifications refer to a logical definition. The different implementations are distinguished 658 by their *behavior* with respect to the NC-SI bus and command operation. The actual physical and internal 659 implementation can vary from the simple diagrams. For example, an implementation can act as if it has 660 separate RX queues without having physically separated memory blocks for implementing those queues.

• S: Single Package, Single Channel

662This implementation has a single NC-SI interface providing NC-SI support for a single LAN port,663all contained within a package or module that has a single connection to the NC-SI physical664bus.

• A: Multiple Logical Packages, Separate Bus Buffers

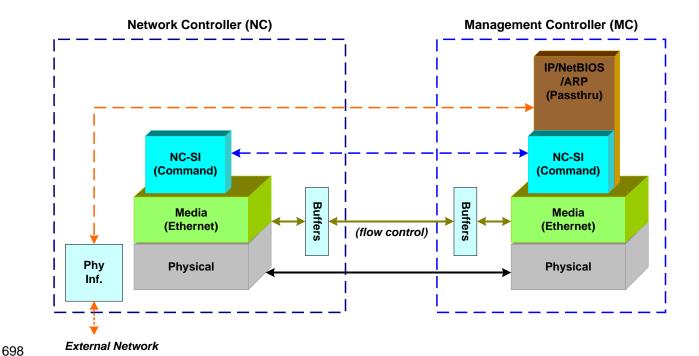

- 666This implementation acts like two physically separate Network Controllers that happen to share667a common overall physical container. Electrically, they behave as if they have separate668electrical buffers connecting to the NC-SI bus. This behavior may be accomplished by means of669a passive internal bus or by separate physical pins coming from the overall package. From the670point of view of the Management Controller and the NC-SI command operation, this671implementation behaves as if the logical controllers were implemented as physically separate672controllers.
- 673This type of implementation may or may not include internal hardware arbitration between the674two logical Network Controller packages. If hardware arbitration is provided external to the675package, it shall meet the requirements for hardware arbitration described later in this676specification. (For more information, see 7.2.)

• B: Single Package, Common Bus Buffers, Separate RX Queues

- 678 In this implementation, the two internal NC-SI channels share a common set of electrical bus buffers. A single Deselect Package command will deselect the entire package. The Channel 679 680 Enable and Channel Disable commands to each channel control whether the channel can 681 transmit Pass-through and AEN packets through the NC-SI interface. The Channel Enable 682 command also determines whether the packets to be transmitted through the NC-SI interface 683 will be queued up in an RX Queue for the channel while the channel is disabled or while the package is deselected. Because each channel has its own RX Queue, this queuing can be 684 configured for each channel independently. 685
- C: Single Package, Common Bus Buffers, Shared RX Queue
- 687This implementation is the same as described in the preceding implementation, except that the688channels share a common RX Queue for holding Pass-through packets to be transmitted689through the NC-SI interface. This queue may or may not also queue up AEN or Response690packets.

691 **5.3 Transport stack**

The overall transport stack of the NC-SI is illustrated in Figure 5. The lowest level is the physical-level
interface (for example, RBT), and the media-level interface is based on Ethernet. Above these interfaces
are the two data-level protocols that are supported by the *NC-SI Specification*: NC-SI Command Protocol
and the Network Data Protocol (for example, ARP, IP, DHCP, and NetBIOS) associated with Passthrough traffic. Both of these protocols are independent from binding to the underlying physical interface.
This specification only defines the binding for NC-SI over RBT.

699

Figure 5 – NC-SI transport stack

This document defines the necessary NC-SI command set and interface specification that allows the appropriate configuration of the Network Controller parameters and operation to enable network traffic to flow to and from external networks to the Management Controller. As shown in Figure 5, the scope of the NC-SI Command Protocol is limited to the internal interface between the Network Controller and the

704 Management Controller.

705 **5.4 Transport protocol**

A simple transport protocol is used to track the reliable reception of command packets. The transport protocol is based upon a command/response paradigm and involves the use of unique Instance IDs (IIDs) in the packet headers to allow responses received to be matched to previously transmitted commands. The Management Controller is the generator of command packets sent to the Sideband Interface of one or more Network Controllers in the system, and it receives response packets from them. A response packet is expected to be received for every command packet successfully sent.

The transport protocol described here shall apply only to command and response packets sent betweenthe Management Controller and the Network Controller.

714 **5.5 Byte and bit ordering for transmission**

Unless otherwise specified, the bytes for a multi-byte numeric field are transmitted most significant byte
 first and bits within a byte are transmitted most significant bit first.

717 6 Operational behaviors

718 This clause describes the NC-SI operating states and typical system-level operation of the NC-SI.

719 6.1 Typical operational model

- This clause describes the typical system-level operation of the NC-SI components.
- The following tasks are associated with Management Controller use of the NC-SI:

• Initial configuration

When the NC-SI interface is first powered up, the Management Controller needs to discover
 and configure NC-SI devices in order to enable pass-through operation. This task includes
 setting parameters such as MAC addresses, configuring Layer 2 filtering, setting Channel
 enables, and so on.

727 • Pass-through

728The Management Controller handles transmitting and receiving Pass-through packets using the729NC-SI. Pass-through packets can be delivered to and received from the network through the730NC-SI based on the Network Controller's NC-SI configuration.

Asynchronous event handling

In certain situations, a status change in the Network Controller, such as a Link State change,
can generate an asynchronous event on the Sideband Interface. These event notifications are
sent to the Management Controller where they are processed as appropriate.

735 • Error handling

736The Management Controller handles errors that may occur during operation or configuration.737For example, a Network Controller may have an internal state change that causes it to enter a738state in which it requires a level of reconfiguration (this condition is called the "Initial State,"739described in more detail in 6.2.4); or a data glitch on the NC-SI could have caused an NC-SI740command to be dropped by the Network Controller, requiring the Management Controller to741retry the command.

742 6.2 State definitions

743 This clause describes NC-SI operating states.

744 6.2.1 General

745 Table 1 describes states related to whether and when the Network Controller is ready to handle NC-SI

command packets, when it is allowed to transmit packets through the NC-SI interface, and when it hasentered a state where it is expecting configuration by the Management Controller.

147 entered a state where it is expecting configuration by the Management Contro

748

Table 1 – NC-SI operating state descriptions

State	Applies to	Description
Interface Power Down	Package	The NC-SI is in the power down state.
Interface Power Up	Package	The NC-SI is in the power up state, as defined in Clause 10.
Package Selected (also referred to as the Selected state)	Package	A Selected package is allowed to turn on its electrical buffers and transmit through the NC-SI interface.
Package Deselected (also referred to as the Deselected state)	Package	A Deselected package is not allowed to turn on its electrical buffers and transmit through the NC-SI interface.
Hardware Arbitration Enabled	Package	When hardware arbitration is enabled, the package is allowed to transmit through the NC-SI interface only when it is Selected and has the TOKEN op-code.

State	Applies to	Description
Hardware Arbitration Disabled	Package	When hardware arbitration is disabled, the package is allowed to transmit through the NC-SI interface anytime that it is Selected, regardless of whether it has the TOKEN op-code.
Package Ready	Package	In the Package Ready state, the package is able to accept and respond to NC-SI commands for the package and be Selected.
Package Not Ready	Package	The Package Not Ready state is a transient state in which the package does not accept package-specific commands.
Channel Ready	Channel	In the Channel Ready state, a channel within the package is able to accept channel-specific NC-SI commands that are addressed to its Channel ID (Package ID + Internal Channel ID).
Channel Not Ready	Channel	The Channel Not Ready state is a transient state in which the channel does not accept channel-specific commands.
Initial State	Channel	In the Initial State, the channel is able to accept and respond to NC-SI commands, and one or more configuration settings for the channel need to be set or restored by the Management Controller (that is, the channel has not yet been initialized, or has encountered a condition where one or more settings have been lost and shall be restored). Refer to 6.2.4 for more information.
Channel Enabled	Channel	This is a sub-state of the Channel Ready state. When a channel is enabled, the channel is allowed to transmit unrequested packets (that is, packets that are not command responses—for example, AEN and Pass-through packets) through the NC-SI interface whenever the package is Selected.
Channel Disabled	Channel	This is a sub-state of the Channel Ready state. When a channel is disabled, the channel is not allowed to transmit unrequested packets (that is, packets that are not command responses—for example, AEN and Pass-through packets) through the NC-SI interface.

749 6.2.2 NC-SI power states

750 Only two power states are defined for the NC-SI:

• NC-SI Interface Power Down state

In this state, the NC-SI Physical interface and the associated receive and transmit buffers in all
 devices on the NC-SI (that is, the NC-SI interfaces on the Network Controllers and Management
 Controller) are not powered up.

• NC-SI Power Up state

756In this state, the NC-SI Physical interface and the associated receive and transmit buffers in all757devices on the NC-SI (that is, the Network Controller and Management Controller) are powered758up. The Network Controller is expected to transition to the Initial State within T4 seconds after759the Power Up state is entered.

760 6.2.3 Package Ready state

A Network Controller in the Package Ready state shall be able to respond to any NC-SI commands that are directed to the ID for the overall package (versus being directed to a particular channel within the package). Package-specific commands are identified by a particular set of Channel ID values delivered in the command header (see 6.2.9).

765 **6.2.4 Initial State**

766 The Initial State for a channel corresponds to a condition in which the NC-SI is powered up and is able to 767 accept NC-SI commands, and the channel has one or more configuration settings that need to be set or 768 restored by the Management Controller. Unless default configuration settings are explicitly defined in this specification, the default values are implementation specific. The MC should not make any assumptions 769 on any configuration settings that are not defined in this specification. Because this state may be entered 770 at any time, the Initial State shall be acknowledged with a Clear Initial State command in order for the 771 772 Initial State to be exited. This requirement helps to ensure that the Management Controller does not continue operating the interface unaware that the NC-SI configuration had autonomously changed in the 773 Network Controller. 774 775 An NC-SI channel in the Initial State shall: 776 be able to respond to NC-SI commands that are directed to the Channel ID for the particular channel (see 6.2.9) 777 respond to all non-OEM command packets that are directed to the channel with a Response 778 Packet that contains a Response Code of "Command Failed" and a Reason Code of 779 780 "Initialization Required" 781 NOTE This requirement does not apply to commands that are directed to the overall package, such as 782 the Select Package and Deselect Package commands. 783 • place the channel into the Disabled state 784 set hardware arbitration (if supported) to "enabled" on Interface Power Up only; otherwise, the setting that was in effect before entry into the Initial State shall be preserved (that is, the 785 hardware arbitration enable/disable configuration is preserved across entries into the Initial 786 787 State) 788 set the enabled/disabled settings for the individual MAC and VLAN filters (typically set using the Set MAC Address, Set VLAN Filter, and Enable VLAN commands) to "disabled" 789 790 It is recommended that global multicast and broadcast filters are "disabled" in the Initial State. NOTE 791 This means that all multicast and broadcast traffic is forwarded to the MC in the Initial State. An 792 implementation may not have the global multicast or broadcast filters in "disabled" state in the 793 Initial State. In this case, the MC may need to explicitly set global multicast and/or broadcast 794 filters prior to enabling receiving pass-through traffic from the NC-SI channel. 795 reset the counters defined in the Get NC-SI Statistics command and the Get NC-SI Pass-• Through Statistics command to 0x0 796 797 disable transmission of Pass-through packets onto the network • 798 NOTE Upon entry into the Initial State, the Channel Network TX setting is also set to "disabled". 799 clear any record of prior command instances received upon entry into the Initial State (that is, • 800 assume that the first command received after entering the Initial State is a new command and 801 not a retried command, regardless of any Instance ID that it may have received before entering the Initial State) 802 disable transmission of AENs 803 • 804 Otherwise, there is no requirement that other NC-SI configuration settings be set, retained, or restored to 805 particular values in the Initial State.

The Initial State is a NC-SI configuration state and therefore places no requirements on the NC's network link state.

808 6.2.5 NC-SI Initial State recovery

As described in 6.2.4, a channel in the Initial State shall receive the Clear Initial State command before other commands can be executed. This requirement ensures that if the Initial State is entered asynchronously, the Management Controller is made aware that one or more NC-SI settings may have changed without its involvement, and blocks the Management Controller from issuing additional commands under that condition. Until the channel receives the Clear Initial State command, the

- 814 Management Controller shall respond to any other received command (except the Select Package and
- 815 Deselect Package commands) with a Command Failed response code and Interface Initialization
- 816 Required reason code to indicate that the Clear Initial State command shall be sent. See response and
- 817 reason code definitions in 8.2.4.1.
- NOTE Package commands (for example, Select Package and Deselect Package) are always accepted and responded to normally regardless of whether the Channel is in the Initial State.

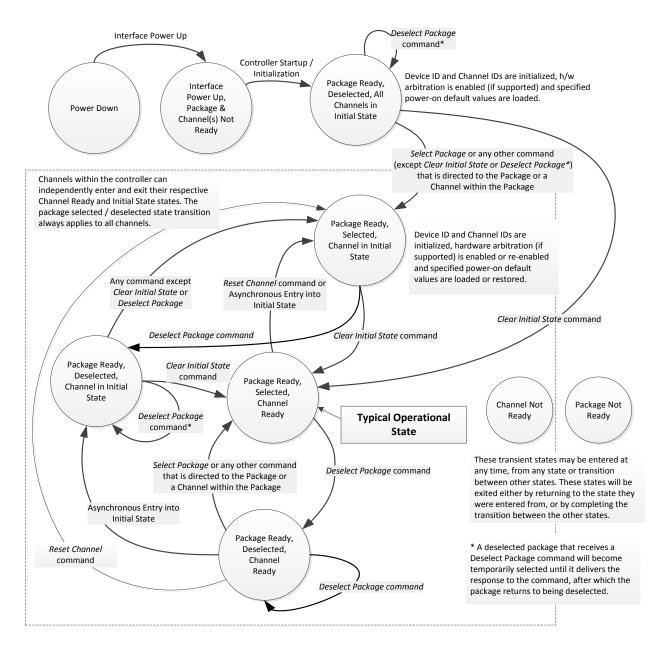

820 If the Management Controller, at any time, receives the response indicating that the Clear Initial State 821 command is expected, it may interpret this response to mean that default settings have been restored for 822 the channel (per the Initial State specification), and that one or more channel settings may need to be 823 restored by the Management Controller.

824 6.2.6 State transition diagram

Figure 6 illustrates the general relationship between the package- and channel-related states described in

Table 1 and the actions that cause transitions between the states. Each bubble in Figure 6 represents a

827 particular combination of states as defined in Table 1.

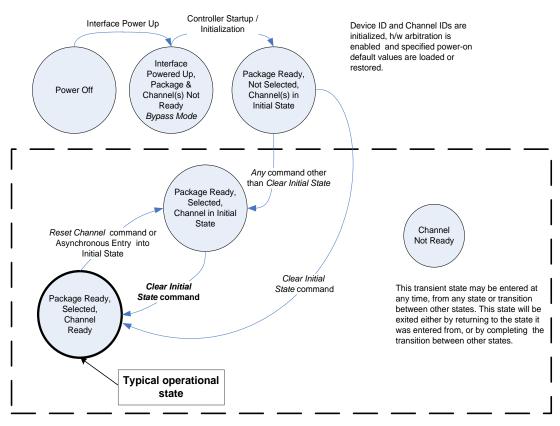

828 829

830

Figure 6 – NC-SI operational state diagram

6.2.7 State diagram for NC-SI operation with hardware arbitration

Figure 7 shows NC-SI operation in the hardware arbitration mode of operation. This is a sub-set of the general NC-SI operational state diagram (Figure 6) and has been included to illustrate the simplified sequence of package selection when this optional capability is used.

Channels within the controller (package) can independently enter and exit their respective Channel States.

835

836

Figure 7 – NC-SI operational state diagram for hardware arbitration operation

837 While Select and Deselect package commands are not shown in Figure 7, these commands can be used 838 with the HW arbitration and will behave as specified in this specification.

839 Select and Deselect package commands can work together with HW arbitration. If HW arbitration is

840 enabled, a package needs both the HW arbitration token and to be selected in order to transmit on the

841 NC-SI. If either the package is deselected or the package does not have HW arbitration token, then the

842 package is not allowed to transmit on the NC-SI.

843 6.2.8 Resets

- Two types of Reset events are defined for the NC-SI Channels:
- Asynchronous Entry into Initial State
- Synchronous Reset
- 847 NOTE Resets that do not affect NC-SI operation are outside the scope of this specification.

848 6.2.8.1 Asynchronous entry into Initial State

An Asynchronous Reset event is defined as an event that results in a Channel asynchronously entering
the Initial State. This event could occur as a consequence of powering up, a System Reset, a Driver
Reset, an Internal Firmware error, loss of Configuration errors, Internal hardware errors, and so on.

- Unless otherwise specified, NC-SI configuration settings beyond those required by the Initial State may or
 may not be preserved following asynchronous entry into the Initial State, depending on the Network
 Controller implementation.
- 855 There is no explicit definition of a Reset for an entire package. However, it is possible that an
- Asynchronous Reset condition may cause an Asynchronous Entry into the Initial State for all Channels in a package simultaneously.

858 6.2.8.2 Synchronous Reset

A Synchronous Reset event on the NC-SI is defined as a Reset Channel command issued by a
 Management Controller to a Channel. Upon the receipt of this command, the Network Controller places
 the Channel into the Initial State.

Unless otherwise specified, NC-SI configuration settings beyond those required by the Initial State may or
 may not be preserved following a Synchronous Reset, depending on the Network Controller
 implementation.

865 6.2.9 Network Controller Channel ID

Each channel in the Network Controller shall be physically assigned a Network Controller Channel ID that
will be used by the Management Controller to specify with which Network Controller channel, of possibly
many, it is trying to communicate. The Network Controller Channel ID shall be physically assignable
(configured) at system-integration time based on the following specification.

- 870 It is the system integrator's or system designer's responsibility to correctly assign and provide these
- identifier values in single- and multi-port Network Controller configurations, and to ensure that Channel
 IDs do not conflict between devices sharing a common NC-SI interconnect.

- The Channel ID field comprises two subfields, Package ID and Internal Channel ID, as described in Table 2.
- 875

Table 2 – Channel ID format

Bits	Field Name	Description
[75]	Package ID	The Package ID is required to be common across all channels within a single Network Controller that share a common NC-SI physical interconnect.
		The system integrator will typically configure the Package IDs starting from 0 and increasing sequentially for each physical Network Controller.
		The Network Controller shall allow the least significant two bits of this field to be configurable by the system integrator, with the most significant bit of this field = $0b$. An implementation is allowed to have all 3 bits configurable.
[40]	Internal Channel ID	The Network Controller shall support Internal Channel IDs that are numbered starting from 0 and increasing sequentially for each Pass-through channel supported by the Network Controller that is accessible by the Management Controller through the NC-SI using NC-SI commands.
		An implementation is allowed to support additional configuration options for the Internal Channel ID as long as the required numbering can be configured.
		An Internal Channel ID value of $0 \times 1F$ applies to the entire Package.

Channel IDs shall be completely decoded. Aliasing between values is not allowed (that is, the NetworkController is not allowed to have multiple IDs select the same channel on a given NC-SI).

878 Once configured, the settings of the Package ID and Internal Channel ID values shall be retained in a 879 non-volatile manner. That is, they shall be retained across power-downs of the NC-SI and shall not be

required to be restored by the Management Controller for NC-SI operation. This specification does not

define the mechanism for configuring or retaining the Package ID or the Internal Channel ID (if

configurable). Some implementations may use pins on the Network Controller for configuring the IDs,

other implementations may use non-volatile storage logic such as electrically-erasable memory or

FLASH, while others may use a combination of pins and non-volatile storage logic.

885 **6.2.10 Configuration-related settings**

This clause presents an overview of the different settings that the Management Controller may need to configure for NC-SI operation.

888 6.2.10.1 Package-specific operation

- 889 Only two configuration settings are package-specific:
- the enable/disable settings for hardware arbitration
- NC-SI flow control
- Hardware arbitration is enabled or disabled through a parameter that is delivered using the Select
 Package command. If hardware arbitration is enabled on all Network Controller packages on the NC-SI,
 more than one package can be in the Selected state simultaneously. Otherwise, only one package is
 allowed to be in the Selected state at a time in order to prevent electrical buffer conflicts (buffer fights)
 that can occur from more than one package being allowed to drive the bus.
- NC-SI flow control is enabled or disabled using the Set NC-SI Flow Control command. The flow control
 setting applies to all channels in the package.

Package-specific commands should only be allowed and executed when the Channel ID field is set to0x1F.

901 6.2.10.2 Channel-specific operation

902 Channel-specific commands should only be allowed to be executed when the Channel ID field is set to a
 903 value other than 0x1F. Channel-specific commands with Invalid Channel IDs should not be allowed or
 904 executed. The recommended command response is Command Failed, Invalid Parameter.

Table 3 shows the major categories of configuration settings that control channel operation when a channel is in the Channel Ready state.

907

908

Table 3 – Channel Ready state configuration settings

Setting/Configuration Category	Description
"Channel Enable" settings	The Enable Channel and Disable Channel commands are used to control whether the channel is allowed to asynchronously transmit unrequested packets (AEN and Pass-through packets) through the NC-SI interface whenever the package is Selected. Note that channels are always allowed to transmit responses to commands sent to the channel.
Pass-through Transmit Enable settings	The Enable Channel Network TX command is used to enable the channel to transmit any Pass-through packets that it receives through the NC-SI onto the network, provided that the source MAC address in those packets matches the Network Controller settings. Correspondingly, the Disable Channel Network TX command is used to direct the controller not to transmit Pass-through packets that it receives onto the network.
AEN Enable settings	The AEN Enable command is used to enable and disable the generation of the different AENs supported by the Network Controller.
MAC Address Filter settings and control	The Set MAC Address, Enable Broadcast Filter, and Enable Global Multicast Filter commands are used to configure the filters for unicast, broadcast, and multicast addresses that the controller uses in conjunction with the VLAN Filter settings for filtering incoming Pass- through packets.
VLAN Filter settings and control	The Set VLAN Filter command is used to configure VLAN Filters that the controller uses in conjunction with the MAC Address Filters for filtering incoming Pass-through packets. The Enable VLAN and Disable VLAN commands are used to configure VLAN filtering modes and enable or disable whether VLAN filtering is used.

909 6.2.11 Transmitting Pass-through packets from the Management Controller

Packets not recognized as command packets (that is, packets without the NC-SI Ethertype) that are
received on the Network Controller's NC-SI interface shall be assumed to be Pass-through packets
provided that the source MAC Address matches one of the unicast MAC addresses settings (as
configured by the Set MAC Address command) for the channel in the Network Controller, and will be
forwarded for transmission to the corresponding external network interface if Channel Network TX is
enabled.

916 6.2.12 Receiving Pass-through packets for the Management Controller

917 The Management Controller has control over and responsibility for configuring packet-filtering options,
918 such as whether broadcast, multicast, or VLAN packets are accepted. Depending on the filter

configurations, after the channel has been enabled, any packet that the Network Controller receives for

the Management Controller shall be forwarded to the Management Controller through the NC-SIinterface.

922 **6.2.13 Startup sequence examples**

923 The following clauses show possible startup sequences that may be used by the Management Controller 924 to start NC-SI operation. Depending upon the specific configuration of each system, there are many 925 possible variations of startup sequences that may be used, and these examples are intended for 926 reference only.

927 6.2.13.1 Typical non hardware arbitration specific startup sequence

The following sequence is provided as an example of one way a Management Controller can start up NC-SI operation. This sequence assumes that the Management Controller has no prior knowledge of how many Network Controllers are hooked to its NC-SI, or what capabilities those controllers support. Note that this is not the only possible sequence. Alternative sequences can also be used to start up NC-SI operation. Some steps may be skipped if the Management Controller has prior knowledge of the Network Controller capabilities, such as whether Network Controllers are already connected and enabled for hardware arbitration.

935 1) **Power up**

The NC-SI is powered up (refer to 10.2.7 for the specification of this condition). The Network 936 Controller packages are provided a Network Controller Power Up Ready Interval during which 937 938 they can perform internal firmware startup and initialization to prepare their NC-SI to accept commands. The Management Controller first waits for the maximum Network Controller Power 939 Up Ready Interval to expire (refer to Table 180). At this point, all the Network Controller 940 packages and channels should be ready to accept commands through the NC-SI. (The 941 942 Management Controller may also start sending commands before the Network Controller Power 943 Up Ready Interval expires, but will have to handle the case that Network Controller devices may 944 be in a state in which they are unable to accept or respond to commands.)

945 2) Discover package

946The Management Controller issues a Select Package command starting with the lowest947Package ID (see 8.4.5 for more information). Because the Management Controller is assumed948to have no prior knowledge of whether the Network Controller is enabled for hardware949arbitration, the Select Package command is issued with the Hardware Arbitration parameter set950to 'disable'.

951 If the Management Controller receives a response within the specified response time, it can record that it detected a package at that ID. If the Management Controller does not receive a 952 953 response, it is recommended that the Management Controller retry sending the command. 954 Three total tries is typical. (This same retry process should be used when sending all commands to the Network Controller and will be left out of the descriptions in the following 955 956 steps.) If the retries fail, the Management Controller can assume that no Network Controller is at 957 that Package ID and can immediately repeat this step 2) for the next Package ID in the 958 sequence.

3) Discover and get capabilities for each channel in the package

960The Management Controller can now discover how many channels are supported in the961Network Controller package and their capabilities. To do this, the Management Controller issues962the Clear Initial State command starting from the lowest Internal Channel ID (which selects a963given channel within a package). If it receives a response, the Management Controller can then964use the Get Version ID command to determine NC-SI specification compatibility, and the Get965Capabilities command to collect information about the capabilities of the channel. The

959

966 967 968		Management Controller can then repeat this step until the full number of internal channels has been discovered. (The Get Capabilities command includes a value that indicates the number of channels supported within the given package.)
969 970 971 972		NOTE The <i>NC-SI Specification</i> requires Network Controllers to be configurable to have their Internal Channel IDs be sequential starting from 0. If it is known that the Network Controller is configured this way, the Management Controller needs only to iterate sequentially starting from Internal Channel
973		ID = 0 up to the number of channels reported in the first Get Capabilities response.
974 975 976		The Management Controller should temporarily retain the information from the Get Capabilities command, including the information that reports whether the overall package supports hardware arbitration. This information is used in later steps.
977	4)	Repeat steps 2 and 3 for remaining packages
978 979		The Management Controller repeats steps 2) and 3) until it has gone through all the Package IDs.
980 981 982 983 984		IMPORTANT: Because hardware arbitration has not been enabled yet, the Management Controller shall issue a Deselect Package command to the present Package ID before issuing the Select Package command to the next Package ID. If hardware arbitration is not being used, only one package can be in the Selected state at a time. Otherwise, hardware electrical buffer conflicts (buffer fights) will occur between packages.
985	5)	Initialize each channel in the package
986 987 988		Based on the number of packages and channels that were discovered, their capabilities, and the desired use of Pass-through communication, the Management Controller can initialize the settings for each channel. This process includes the following general steps for each package:
989		a) Issue the Select Package command.
990 991		b) For each channel in the package, depending on controller capabilities, perform the following actions. Refer to individual command descriptions for more information.
992 993 994		 Use the Set MAC Address command to configure which unicast and multicast addresses are used for routing Pass-through packets to and from the Management Controller.
995 996		 Use the Enable Broadcast Filter command to configure whether incoming broadcast Pass-through packets are accepted or rejected.
997 998 999		 Use the Enable Global Multicast Filter command to configure how incoming multicast Pass-through packets are handled based on settings from the Set MAC Address command.
1000 1001		 Use the Set VLAN Filter and Enable VLAN Filters commands to configure how incoming Pass-through packets with VLAN Tags are handled.
1002 1003 1004		 Use the Set NC-SI Flow Control command (if supported) to configure how Ethernet Pause Frames are used for flow control on the NC-SI. Note: Set NC-SI Flow Control is a package command and only need to be issued once
1005 1006		 Use the AEN Enable command to configure what types of AEN packets the channel should send out on the NC-SI.
1007 1008 1009 1010		• Use the Enable Channel Network TX command to configure whether the channel is enabled to deliver Pass-through packets from the NC-SI to the network (based on the MAC address settings) or is disabled from delivering any Pass-through packets to the network.

1011 c) Issue the Deselect Package command.

1012 6) Start Pass-through packet and AEN operation on the channels

1013The channels should now have been initialized with the appropriate parameters for Pass-1014through packet reception and AEN operation. Pass-through operation can be started by issuing1015the Enable Channel command to each channel that is to be enabled for delivering Pass-through1016packets or generating AENs through the NC-SI interface.

1017NOTEIf hardware arbitration is not operational and it is necessary to switch operation over to another1018package, a Deselect Package command shall be issued to the presently selected package1019before a different package can be selected. Deselecting a package blocks all output from the1020package. Therefore, it is not necessary to issue Disable Channel commands before selecting1021another package. There is no restriction on enabling multiple channels within a package.

1022 **6.2.13.2 Hardware arbitration specific startup sequence**

1023 This clause applies when multiple NCs are used by the MC. This clause only applies to the NC-SI over 1024 RBT binding.

1025 The following is an example of the steps that a Management Controller may perform to start up NC-SI

1026 operation when Hardware Arbitration is specifically known to be used, present, and enabled on all

1027 Network Controllers. This example startup sequence assumes a high level of integration where the

1028 Management Controller knows the Network Controllers support and default to the use of Hardware

Arbitration on startup, but does not have prior knowledge of how many Network Controllers are interfaced

1030 to the NC-SI, or the full set of capabilities those controllers support, so discovery is still required.

Although other startup examples may show a specific ordering of steps for the process of discovering, configuring and enabling channels, the Management Controller actually has almost total flexibility in choosing how these steps are performed once a channel in a package is discovered. In the end, it would be just as valid for a Management Controller to follow a breadth-first approach to discovery steps as it would be to follow a depth-first approach where each channel that is discovered is fully initialized and enabled before moving to the next.

1037 1) **Power up**

1038 No change from other startup scenarios.

1039 2) Discovery

1040The process of discovery consists of identifying the number of packages that are available, the1041number of channels that are available in each package, and for each channel, the capabilities1042that are provided for Management Controller use. Because, in this startup scenario, the1043Management Controller knows Hardware Arbitration is used, it is not required to use the Select1044Package and Deselect Package commands for discovery, but may elect to just use the Clear1045Initial State command for this purpose instead.

1046 In this startup scenario, Packages and Channels are discovered by sending the Clear Initial 1047 State command starting with the lowest Package ID and Channel ID, then waiting for, and recording, the response event as previously described. Internal channel IDs are required to be 1048 numbered sequentially starting with 0, so when the Management Controller does not receive a 1049 1050 response to repeated attempts at discovery, it knows this means no additional channels exist in 1051 the current package. If this happens when the internal channel ID is 0, the Management Controller knows a package is not available at the current package ID, and it continues with the 1052 1053 next package ID in sequence. If the Management Controller receives a response to the Clear 1054 Initial State command, it records that the channel and package are available, and continues 1055 discovery.

1056During discovery, the Management Controller should interrogate the capabilities of each1057channel found to be available in each package by sending the **Get Capabilities** command1058appropriate package and channel ID values. However, it does not matter whether this is done1059as the very next step in the discovery process, or performed for each channel after all packages1060and channels have been discovered, just as long as the Management Controller does1061interrogate each channel.

1062 3) Configure each channel and enable pass-through

1063 Once the existence of all packages and channels, and the capabilities of each channel, have been discovered and recorded, the Management Controller shall initialize and enable each 1064 channel as needed for use. The details of these steps remain essentially the same as have 1065 been previously stated. except to note that there are no restrictions on how they are performed. 1066 What this means is that the MC may perform these steps in any order across the channels in 1067 each package as it sees fit. The MC may fully initialize and enable each channel in each 1068 package one at a time, or perform the same step on each channel in sequence before moving 1069 1070 on to the next, or in a different order. The specific order of steps is not dictated by this 1071 specification.

1072 **6.2.13.3 Summary of scheme for the MC without prior knowledge of hardware arbitration**

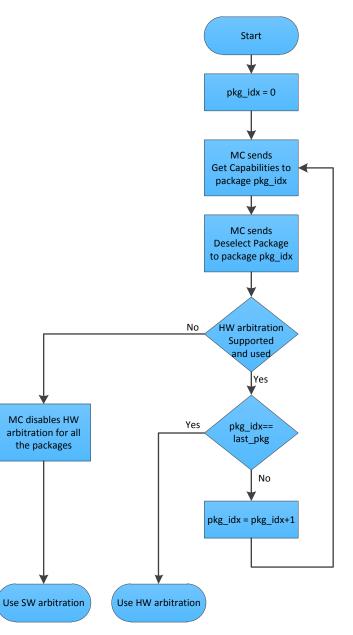

1073 The following scheme describes the case when the MC does not have a priori knowledge of the hardware 1074 arbitration support across multiple NCs.

1075 1. For each available NC,

1076

1077

- a. The MC checks whether a device supports the HW arbitration, using "Get Capabilities" commands (this implicitly selects the package).
- 1078b. The MC issues "Deselect Package" for the NC (needed as at this stage we do not know1079whether all the devices support HW arbitration).
- 1080 2. If (all NCs support HW arbitration and the HW arbitration is used by all NCs), then
- 1081the MC assumes that HW arbitration is active because according to clause 6.2.4 "set1082hardware arbitration (if supported) to *enabled* on Interface Power Up only", and the MC can1083"Select" any number of packages at the same time.
- 1084 Otherwise (at least one NC reports that HW arbitration is not supported, or at least one NC reports that HW arbitration is not used, or at least one NC cannot report its support level)
- 1086The HW arbitration is **not** active, and the MC can "Select" only single package at the any1087time.
- 1088The MC configures each and every NC to disable HW arbitration, using the "Select1089Package" command.

1092 6.3 NC-SI traffic types

- 1093 Two types of traffic are carried on the NC-SI: Pass-through traffic and Control traffic.
- Pass-through traffic consists of packets that are transferred between the external network
 interface and the Management Controller using the NC-SI.
- Control traffic consists of commands (requests) and responses that support the configuration and control of the NC-SI and Pass-through operation of the Network Controller, and AENs that support reporting various events to the Management Controller.

1099 6.3.1 Command protocol

Commands are provided to allow a Management Controller to initialize, control, and regulate
 Management Controller packet flow across the NC-SI, configure channel filtering, and to interrogate the
 operational status of the Network Controller. As interface master, the Management Controller is the
 initiator of all commands, and the Network Controller responds to commands.

1104 **6.3.1.1 Instance IDs**

1105 The command protocol uses a packet field called the Instance ID (IID). IID numbers are 8-bit values that 1106 shall range from 0×01 to $0 \times FF$. IIDs are used to uniquely identify instances of a command, to improve the 1107 robustness of matching responses to commands, and to differentiate between new and retried 1108 commands. The Network Controller that receives a command handles the IID in the following ways:

- It returns the IID value from the command in the corresponding response.
- If the IID is the same as the IID for the previous command, it recognizes the command as a 'retried' command rather than as a new instance of the command. It is expected that the 'retried' command contains the same command type value in the Control Message Type field. The NC behavior when a 'retried' command type does not match the original command type is outside the scope of this specification.
- If a retried command is received, the Network Controller shall return the previous response.
 Depending on the command, the Network Controller can accomplish this either by holding the previous response data so that it can be returned, or, if re-executing the command has no side effects (that is, the command is idempotent), by re-executing the command operation and returning that response.
- 1120 If the command IID is the same as the IID for the previous command, and the Poll Indication is • 1121 set, the NC recognizes the command as a 'polling' command rather than as a new instance of 1122 the command. When polling, the MC is expected to use the command type value of the original command in the Control Packet Type field. If there was no command in progress, the NC shall 1123 fail the 'polling' command and respond with an error. If the command type of command with Poll 1124 1125 shall fail the 'polling' command and respond with an error. When the NC fails the 'polling' 1126 command, the outcome of the original command is indeterminate and is outside the scope of this specification. 1127
- If a command with Poll Indication set is received and the original command has completed, then the Network Controller shall return the response of the completed command. If it is still processing the command, it shall return a "Delayed Response" code and optionally a recommended next polling time response.
- When an IID value is received that is different from the one for the previous command, the Network Controller executes the command as a new command.
- When the NC-SI Channel first enters the Initial State, it clears any record of any prior requests. That is, it assumes that the first command after entering the Initial State is a new command and

1136not a retried command, regardless of any IID that it may have received before entering the Initial1137State.

1138 Thus, for single-threaded operation with idempotent commands, a responding Network Controller can 1139 simply execute the command and return the IID in the response that it received in the command. If it is 1140 necessary to not execute a retried command, the responding controller can use the IID to identify the 1141 retried command and return the response that was delivered for the original command.

- 1142 The Management Controller that generates a command handles the IID in the following ways:
- The IID changes for each new instance of a command.
- If a command needs to be retried, the Management Controller uses the same value for the IID that it used for the initial command.
- The Management Controller can optionally elect to use the IID as a way to provide additional confirmation that the response is being returned for a particular command.
- 1148 Because an AEN is not a response, an AEN always uses a value of 0x00 for its IID.
- 1149 NOTE The Instance ID mechanism can be readily extended in the future to support multiple controllers and multiple 1150 outstanding commands. This extension would require having the responder track the IID on a per command 1151 and per requesting controller basis. For example, a retried command would be identified if the IID and 1152 command matched the IID and command for a prior command for the given originating controller's ID. That 1153 is, a match is made with the command, originating controller, and IID fields rather than on the IID field alone. 1154 A requester that generates multiple outstanding commands would correspondingly need to track responses 1155 based on both command and IID in order to match a given response with a given command. IIDs need to be 1156 unique for the number of different commands that can be concurrently outstanding.

1157 **6.3.1.2 Single-threaded operation**

1158 The Network Controller is required to support NC-SI commands only in a single-threaded manner. That is, 1159 the Network Controller is required to support processing only one command at a time, and is not required 1160 to accept additional commands until after it has sent the response to the previous one.

1161 Therefore, the Management Controller should issue NC-SI commands in a single-threaded manner. That

1162 is, the Management Controller should have only one command outstanding to a given Network Controller

1163 package at a time. Upon sending an NC-SI command packet, and before sending a subsequent 1164 command, the Management Controller should wait for the corresponding response packet to be received

1164 command, the Management Controller should wait for the corresponding response packet to be received or a command timeout event to occur before attempting to send another command. For the full

- 1165 or a command timeout event to occur before attempting to send another command. F
- 1166 descriptions of command timeout, see 6.9.2.1.

1167 **6.3.1.3 Responses**

- 1168 The Network Controller shall process and acknowledge each validly formatted command received at the 1169 NC-SI interface by formatting and sending a valid response packet to the Management Controller through 1170 the NC-SI interface.
- 1171 To allow the Management Controller to match responses to commands, the Network Controller shall copy 1172 the IID number of the Command into the Instance ID field of the corresponding response packet.
- 1173 To allow for retransmission and error recovery, the Network Controller may re-execute the last command
- 1174 or maintain a copy of the response packet most recently transmitted to the Management Controller
- 1175 through its NC-SI interface. This "previous" response packet shall be updated every time a new response 1176 packet is transmitted to the Management Controller by replacing it with the one just sent.
- 4477 The Network Controller response shall return a "Command Unsurported" response and with an
- 1177 The Network Controller response shall return a "Command Unsupported" response code with an
- 1178 "Unknown Command Type" reason code for any command (standard or OEM) that the Network Controller 1179 does not support or recognize.
 - Version 1.2.0_2b

1180 **6.3.1.4 Response and post-response processing**

1181 Typically, a Network Controller completes a requested operation before sending the response. In some 1182 situations, however, it may be useful for the controller to be allowed to queue up the requested operation 1183 and send the response assuming that the operation will complete correctly (for example, when the 1184 controller is requested to change link configuration). The following provisions support this process:

- A Network Controller is allowed to send a response before performing the requested action if the command is expected to complete normally and all parameters that are required to be returned with the response are provided.
- Temporal ordering of requested operations shall be preserved. For example, if one command updates a configuration parameter value and a following command reads back that parameter, the operation requested first shall complete so that the following operation returns the updated parameter.
- Under typical operation of the Network Controller, responses should be delivered within the Normal Execution Interval (T5) (see Table 180).
- Unless otherwise specified, all requested operations shall complete within the Asynchronous Reset/Asynchronous Not Ready interval (T6) following the response.
- If the Network Controller channel determines that the requested operation or configuration
 change has not been completed correctly after sending the response, the channel shall enter
 the Initial State.
- If the command response is dependent on the execution of the command and the command response cannot be provided within Normal Execution Interval (T5), then a "Delayed Response" response code may be returned. In this case, the MC can poll the command later with the "Poll Indication" set to retrieve the response. The decision on when the MC polls again can be based on one of the following criteria:
- A fixed delay. In this case it is recommended to use a delay greater than T5
- If provided, based on the "recommended next polling time" in the original response
- If AEN is enabled, based on reception of a "Delayed Response Ready AEN"
- When using delayed responses, the NC shall complete the command processing within T14 sec.

1209 6.3.1.5 NC-SI traffic ordering

1210 This specification does not require any ordering between AENs, NC-SI responses, and NC-SI Pass-1211 through packets. Specific transport binding specifications may require ordering between AENs, NC-SI 1212 responses, and NC-SI Pass-through packets.

1213 **6.4 Link configuration and control**

- 1214 The Network Controller provides commands to allow the Management Controller to specify the 1215 auto-negotiation, link speed, duplex settings, and so on to be used on the network interface. For more
- 1216 information, see 8.4.21.
 - 1217NOTEThe Management Controller should make link configuration changes only when the host network driver is
absent or non-operational.

1219 **6.4.1 Link Status**

1220 The Network Controller provides a Get Link Status command to allow the Management Controller to 1221 interrogate the configuration and operational status of the primary Ethernet links. The Management

1222 Controller may issue the Get Link Status command regardless of OS operational status.

1223 6.5 Frame filtering for Pass-through mode

The Network Controller provides the option of configuring various types of filtering mechanisms for the
purpose of controlling the delivery of received Ethernet frames to the Management Controller. These
options include VLAN Tag filter, L2 address filters, MAC address support, and limited frame filtering using
L3, L4 protocol header fields. All frames that pass frame filtering are forwarded to the Management
Controller over the NC-SI.

1229 6.5.1 Multicast filtering

The Network Controller may provide commands to allow the Management Controller to enable and
disable global filtering of all multicast packets. The Network Controller may optionally provide one or more
individual multicast filters, as well as DHCP v6, IPv6 Neighbor Advertisement, IPv6 Router Advertisement,
IPv6 Neighbor Solicitation, and IPv6 MLD filters.

1234 6.5.2 Broadcast filtering

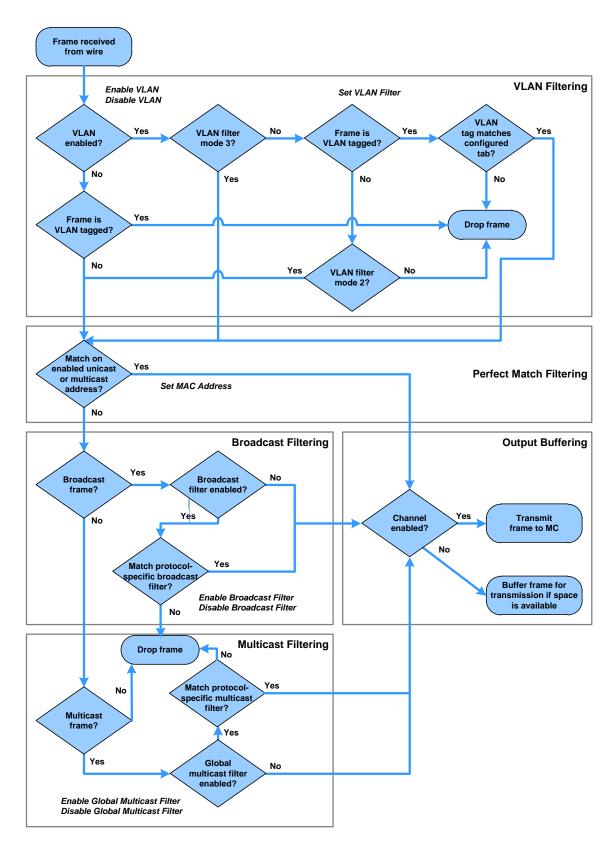

1235 The Network Controller provides commands to allow the Management Controller to enable and disable 1236 forwarding of Broadcast and ARP packets. The Network Controller may optionally support selective

1237 forwarding of broadcast packets for specific protocols, such as DHCP and NetBIOS.

1238 6.5.3 VLAN filtering

1239 The Network Controller provides commands to allow the Management Controller to enable and disable 1240 VLAN filtering, configure one or more VLAN Filters, and to configure VLAN filtering modes.

Figure 9 illustrates the flow of frame filtering. Italicized text in the figure is used to identify NC-SI command names.

1244

Figure 9 – NC-SI packet filtering flowchart

1245 6.6 Output buffering behavior

- 1246 There are times when the NC is not allowed to transmit Pass-through, AEN, or Control Messages onto 1247 the NC-SI.
- 1248 The NC should buffer Pass-through frames to be transmitted to the MC under any of the following 1249 conditions:
- 1250 The package is deselected.
- For a channel within a package while that channel is disabled.
- When the hardware arbitration is enabled and the NC does not have the token to transmit frames to the MC.
- 1254 The NC may buffer AENs to the MC under any of the above conditions.
- 1255 Control Messages (responses) are buffered when hardware arbitration is enabled and the NC does not 1256 have the token to transmit frames to the MC.
- Additionally, while an NC-SI channel is in the initial state, previously received Pass-through frames and AENs may or may not be buffered. This behavior is outside the scope of this specification.

1259 6.7 NC-SI flow control

The Network Controller may provide commands to enable flow control on the NC-SI between the Network
 Controller and the Management Controller. The NC-SI flow control behavior follows the PAUSE frame
 behavior as defined in the <u>IEEE 802.3 specification</u>. Flow control is configured using the Set NC-SI Flow
 command (see 8.4.41).

1264 6.8 Asynchronous Event Notification

Asynchronous Event Notification (AEN) packets enable the Network Controller to deliver unsolicited
notifications to the Management Controller when certain status changes that could impact interface
operation occur in the Network Controller. Because the NC-SI is a small part of the larger Network
Controller, its operation can be affected by a variety of events that occur in the Network Controller. These
events include link status changes, OS driver loads and unloads, and chip resets. This feature defines a
set of notification packets that operate outside of the established command-response mechanism.

- 1271 Control over the generation of the AEN packets is achieved by control bits in the AEN Enable command.1272 Each type of notification is optional and can be independently enabled by the Management Controller.
- AENs are not acknowledged, and there is no protection against the possible loss of an AEN packet. Each defined event has its own AEN packet. Because the AEN packets are generated asynchronously by the Network Controller, they cannot implement some of the features of the other Control Messages. AEN packets leverage the general packet format of Control Messages.
- The originating Network Controller channel shall fill in its Channel ID (Ch. ID) field in the command header to identify the source of notification.
- The IID field in an AEN shall be set to 0x00 to differentiate it from a response or command packet.
- The Network Controller shall copy the AEN MC ID field from the AEN Enable command into the MC ID field in every AEN sent to the Management Controller.

1283 6.9 Error handling

1284 This clause describes the error-handling methods that are supported over the NC-SI. Two types of error-1285 handling methods are defined:

- Synchronous Error Handling
- Errors that trigger Asynchronous Entry into the Initial State
- Synchronous Error Handling occurs when an Error (non-zero) Response/Reason Code is received in
 response to a command issued by the Management Controller. For information about response and
 reason codes, see 8.2.4.1.
- 1291 Asynchronous Entry into the Initial State Error Handling occurs when the Network Controller
- 1292 asynchronously enters the Initial State because of an error condition that affects NC-SI configuration or a 1293 failure of a command that was already responded to. For more information, see 6.2.8.1.

1294 6.9.1 Transport errors

1295 Transport error handling includes the dropping of command packets. Data packet errors are out of the 1296 scope of this specification.

1297 6.9.1.1 Dropped Control Messages

- 1298 The Network Controller shall drop Control Messages received on the NC-SI interface only under the 1299 following conditions:
- The packet has an invalid Frame Check Sequence (FCS) value.
- Frame length does not meet <u>IEEE 802.3</u> requirements (except for OEM commands, where accepting larger packets may be allowed as a vendor-specific option).
- The packet checksum (if provided) is invalid.
- The NC-SI Channel ID value in the packet does not match the expected value.
- The Network Controller does not have resources available to accept the packet.
- The Network Controller receives a command packet with an incorrect header revision.
- 1307 The Network Controller may also drop Control Messages if an event that triggers Asynchronous Entry into 1308 the Initial State causes packets to be dropped during the transition.

1309 **6.9.2 Missing responses**

- 1310 There are typical scenarios in which the Management Controller may not receive the response to a 1311 command:
- The Network Controller dropped the command and thus never sent the response.
- The response was dropped by the Management Controller (for example, because of a CRC error in the response packet).
- The Network Controller is in the process of being reset or is disabled.

1316 The Management Controller can detect a missing response packet as the occurrence of an NC-SI1317 command timeout event.

1318 **6.9.2.1 Command timeout**

1319 The Management Controller can detect missing responses by implementing a command timeout interval.

The timeout value chosen by the Management Controller shall not be less than Normal Execution
 Interval, T5. Upon detecting a timeout condition, the Management Controller should not make

1322 assumptions on the state of the unacknowledged command (for example, the command was dropped or

1323 the response was dropped), but should retransmit (retry) the previous command using the same IID it 1324 used in the initial command.

1325 The Management Controller should try a command at least three times before assuming an error 1326 condition in the Network Controller.

1327 It is possible that a Network Controller could send a response to the original command at the same time a 1328 retried command is being delivered. Under this condition, the Management Controller could get more than 1329 one response to the same command. Thus, the Management Controller should be capable of determining 1330 that it has received a second instance of a previous response packet. Dropped commands may be 1331 detected by the Management Controller as a timeout event waiting for the response.

1332 **6.9.2.2** Handling dropped commands or missing responses

1333 To recover from dropped commands or missing responses, the Management Controller can retransmit 1334 the unacknowledged command packet using the same IID that it used for the initial command.

1335The Network Controller shall be capable of reprocessing retransmitted (retried) commands without error1336or undesirable side effects. The Network Controller can determine that the command has been

1337 retransmitted by verifying that the IID is unchanged from the previous command.

1338 **6.9.3 Detecting Pass-through traffic interruption**

The Network Controller might asynchronously enter the Initial State because of a reset or other event. In this case, the Network Controller stops transmitting Pass-through traffic on the RXD lines. Similarly, Passthrough traffic sent to the Network Controller may be dropped. If the Management Controller is not in the state of sending or receiving Pass-through traffic, it may not notice this condition. Thus the Management Controller should periodically issue a command to the Network Controller to test whether the Network Controller has entered the Initial State. How often this testing should be done is a choice of the Management Controller.

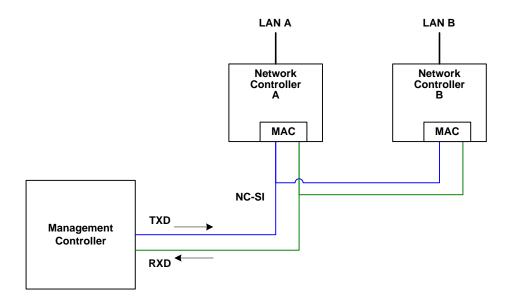

Arbitration in configurations with multiple Network Controller packages

This clause applies to NC-SI over RBT only. More than one Network Controller package on an NC-SI
over RBT can be enabled for transmitting packets to the Management Controller. This specification
defines two mechanisms to accomplish Network Controller package arbitration operations. One
mechanism uses software commands provided by the Network Controller for the Management Controller
to control whose turn it is to transmit traffic. The other mechanism uses hardware arbitration to share the
single RBT bus. Implementations are required to support command-based Device Selection operation;
the hardware arbitration method is optional.

1355 **7.1 General**

Figure 10 is a simplified block diagram of the Sideband Interface being used in a multi-drop configuration.
The RMII (upon which NC-SI is based) was originally designed for use as a point-to-point interconnect.
Accordingly, only one party can transmit data onto the bus at any given time. There is no arbitration

1359 protocol intrinsic in the RMII to support managing multiple transmitters.

1361

Figure 10 – Basic multi-drop block diagram

1362 However, it is possible for multiple Network Controllers on the interface to be able to simultaneously

receive traffic from the Management Controller that is being transmitted on the NC-SI TXD lines. The 1363

1364 Network Controllers can receive commands from the Management Controller without having to arbitrate

1365 for the bus. This facilitates the Management Controller in delivering commands for setup and

1366 configuration of arbitration.

- 1367 Arbitration allows multiple Network Controller packages that are attached to the interface to be enabled to 1368 share the RXD lines to deliver packets to the Management Controller.
- 1369 This operation is summarized as follows:
- 1370 • Only one Network Controller at a time can transmit packets on the RXD lines of the interface.
- 1371 Network Controllers can accept commands for configuring and controlling arbitration for the . RXD lines. 1372

7.2 Hardware arbitration 1373

1374 To prevent two or more NC-SI packages from transmitting at the same time, a hardware-based arbitration 1375 scheme was devised to allow only one Network Controller package to drive the RX lines of the shared interface at any given time. This scheme uses a mechanism of passing messages (op-codes) between 1376 1377 Network Controller packages to coordinate when a controller is allowed to transmit through the NC-SI interface. 1378

7.2.1 General 1379

1380 Three conceptual modes of hardware arbitration exist: arbitration master assignment, normal operation, 1381 and bypass. After a package is initialized and has its Channel IDs assigned, it enters the arbitration 1382 master assignment mode. This mode assigns one package the role of an Arbitration Master (ARB Master) that is responsible for initially generating a TOKEN op-code that is required for the normal 1383 1384 operating mode. In the normal operating mode, the TOKEN op-code is passed from one package to the next in the ring. The package is allowed to use the shared RXD signals and transmit if the package has 1385

received the TOKEN op-code and has a packet to send. 1386

Bypass mode allows hardware arbitration op-codes to pass through a Network Controller package before it is initialized. Bypass mode shall be in effect while hardware arbitration is disabled. Bypass mode shall be exited and arbitration master assignment mode shall be entered when the hardware arbitration

1390 becomes enabled or re-enabled.

1391 Hardware-based arbitration requires two additional pins (ARB_IN and ARB_OUT) on the Network

1392 Controller. The ARB_OUT pin of one package is connected to the ARB_IN pin of the next package to 1393 form a ring configuration, as illustrated in Figure 11. The timing requirements for hardware arbitration are

designed to accommodate a maximum of four Network Controller packages. If the implementation

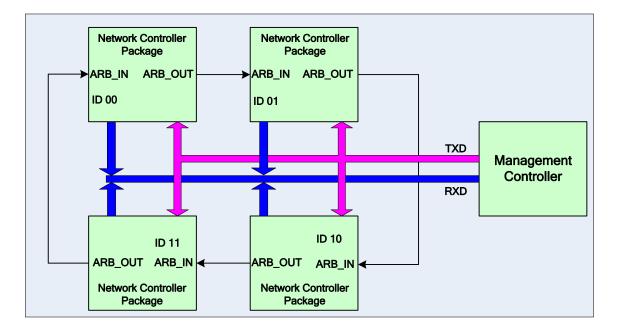

1395 consists of a single Network Controller package, the ARB_OUT pin may be connected to the ARB_IN pin

1396 on the same package, or may be left disconnected, in which case hardware arbitration should be disabled

1397 by using the Select Package command. This specification optionally supports reporting of Hardware

arbitration implementation status and hardware arbitration status using the **Get Capabilities** command.

1399

1400

1401

Figure 11 – Multiple Network Controllers in a ring format

Each Network Controller package sends out pulses on the ARB_OUT pin to create a series of symbols
that form op-codes (commands) between Network Controllers. Each pulse is one clock wide and
synchronized to REF_CLK. The hardware arbitration data bits follow the same timing specifications used
for the TXD and RXD data bits (see 10.2.6). The pulses are di-bit encoded to ensure that symbols are
correctly decoded. The symbols have the values shown in Table 4.

While clause 7.2.2.1 allows for op-code to be truncated, it is recommended that the transmission of
current op-code on ARB_OUT be completed if the HW arbitration mode is changed in the middle of an
op-code transfer (or in the middle of a symbol).

Table 4 – Hardware arbitration di-bit encoding

Symbol Name	Encoded Value
Esync	11b
Ezero	00b
Eone	01b
Illegal symbol	10b

1411 **7.2.2 Hardware arbitration op-codes**

- 1412 The hardware-based arbitration feature has five defined op-codes: IDLE, TOKEN, FLUSH, XON, and
- 1413 XOFF. Each op-code starts with an Esync symbol and is followed by either E_{one} or E_{zero} symbols. The 1414 legal op-codes are listed in Table 5.

1415

Table 5 – Hardware arbitration op-code format

Op-Code	Format	
IDLE	E _{sync} E _{zero} (110000b)	
TOKEN	E _{sync} E _{one} E _{zero} (110100b)	
FLUSH	E _{sync} E _{one} E _{zero} E(Package_ID[2:0]) E _{zero} (11010100xxxxx00b)	
XOFF	E _{sync} E _{zero} E _{one} E _{zero} E _{zero} (11000100000b)	
XON	Esync Ezero Eone Ezero E(Package_ID[2:0]) Ezero (1100010100uuuuuu00b)	

1416 **7.2.2.1 Detecting truncated op-codes**

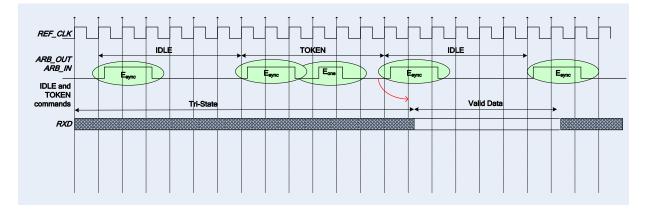

- A truncated op-code is detected when the number of clocks between E_{sync}s is less than the number of bits required for the op-code. Note that any additional bits clocked in after a legitimate op-code is detected do
- 1419 not indicate an error condition and are ignored until the next E_{sync}.

1420 **7.2.2.2 Handling truncated or illegal op-codes**

1421 When a Network Controller receives a truncated or illegal op-code, it should discard it.

1422 **7.2.2.3** Relationship of op-codes processing and driving the RX data lines

- A Network Controller package shall take no more than T9 REF_CLK times after receiving the last bit of the op-code to decode the incoming op-code and start generating the outgoing op-code. This time limit allows for decoding and processing of the incoming op-code under the condition that an outgoing op-code
- 1426 transmission is already in progress.
- 1427 A package that has received a TOKEN and has packet data to transmit shall turn on its buffer and begin
- 1428 transmitting the packet data within T11 REF_CLK times of receiving the TOKEN, as illustrated in
- 1429 Figure 12. The package shall disable the RXD buffers before the last clock of the transmitted TOKEN.

1431

Figure 12 – Op-code to RXD relationship

1432 **7.2.3 Op-code operations**

1433 This clause describes the behavior associated with the five defined op-codes.

1434 **7.2.3.1 TOKEN op-code**

When a TOKEN op-code is received, the Network Controller package may drive the RXD signals to send
only one of the following items: a Pass-through packet, a command response, or an AEN. One <u>IEEE</u>
<u>802.3</u> PAUSE frame (XON or XOFF) may also be sent either before or after one of the previous packets,
or on its own. While the Network Controller package is transmitting the data on the RXD signals of the
interface, it shall generate IDLE op-codes on its ARB_OUT pin. Once a package completes its
transmission, if any, it shall generate and send the TOKEN on its ARB_OUT pin.

1441 **7.2.3.2 IDLE op-code**

1442 A package that has no other op-code to send shall continuously generate IDLE op-codes. Typically, a

1443 received IDLE op-code indicates that the TOKEN is currently at another package in the ring. This op-code

1444 is also used in the ARB_Master assignment process (for details, see 7.2.5).

1445 **7.2.3.3 FLUSH op-code**

A FLUSH op-code is used to establish an Arbitration Master for the ring when the package enters the
 Package Ready state or when the TOKEN is not received within the specified timeout, T8. This op-code
 is further explained in 7.2.5.

If the package receives a FLUSH op-code while it is in the middle of transmitting a packet onto NC-SI, it
 shall generate IDLE op-codes until the transmission is complete and then process the FLUSH op-code as
 described.

14527.2.3.4Flow Control op-codes

1453 The XON and XOFF op-codes are used to manage the generation of <u>IEEE 802.3</u> PAUSE frames on the 1454 NC-SI. If the Network Controller supports flow control and flow control is enabled, the XOFF and XON 1455 op-codes behave as described in this clause. If the Network Controller does not support flow control or if 1456 flow control is not enabled, the Network Controller shall pass the op-codes to the next package.

1457 There may be a configuration where some NCs support flow control and others do not. In this

1458 configuration, an NC sending an XOFF op-code may see the XOFF packet emission delayed by two or

1459 more full size Pass-through packets, one for each package not supporting XOFF when it gets the token,

and one for the next package supporting XOFF before sending the XOFF packet. The NC is not required
 to provide buffering to prevent packet loss in this configuration. No drop behavior should be expected by
 an MC only if all NCs have flow control enabled.

- 1463NOTEThere is a maximum amount of time that the Network Controller may maintain a PAUSE. For more1464information, see 8.4.41.
- 1465 XOFF op-code
- A Network Controller package that becomes congested while receiving packets from the NC-SI shallperform the following actions:
- If it does not have a TOKEN, it sends the XOFF op-code to the next package.
- If it has the TOKEN and has not previously sent an XOFF frame for this instance of congestion, it shall send a single XOFF frame (PAUSE frame with a pause time of 0xFFFF) and will not generate an XOFF op-code.
- A package may also regenerate an XOFF frame or op-code if it is still congested and determines that the present PAUSE frame is about to expire.
- 1474 When a package on the ring receives an XOFF op-code, it shall perform one of the following actions:
- If it does not have a TOKEN op-code, it passes the XOFF op-code to the next package in the ring.
- If it has the TOKEN, it shall send an XOFF frame (PAUSE frame with a pause time of 0xFFFF)
 and will not regenerate the XOFF op-code. If it receives another XOFF op-code while sending
 the XOFF frame or a regular network packet, it discards the received XOFF op-code.

1480 7.2.3.4.1 XON op-code

- 1481XON frames (PAUSE frame with a pause time of 0×0000) are used to signal to the Management1482Controller that the Network Controller packages are no longer congested and that normal traffic flow can1483resume. XON op-codes are used between the packages to coordinate XON frame generation. The1484package ID is included in this op-code to provide a mechanism to verify that every package is not1485congested before sending an XON frame to the Management Controller.
- 1486 The XON op-code behaves as follows:
- 1487 When a package is no longer congested, it generates an XON op-code with its own Package 1488 ID. This puts the package into the 'waiting for its own XON' state. 1489 • A package that receives the XON op-code takes one of the following actions: 1490 If it is congested, it replaces the received XON op-code with the IDLE op-code. This action 1491 causes the XON op-code to be discarded. Eventually, the congested package generates 1492 its own XON op-code when it exits the congested state. 1493 If the package is not congested and is not waiting for the XON op-code with own Package 1494 ID, it forwards the received XON op-code to the next package in the ring. 1495 NOTE If the received XON op-code contains the package's own Package ID, the op-code should 1496 be discarded. 1497 If the package is not congested and is waiting for its own XON op-code, it performs one of the following actions: 1498 1499 If it receives an XON op-code with a Package ID that is higher than its own, it replaces 1500 the XON op-code with its own Package ID. 1501 If it receives an XON op-code with a Package ID lower than its own, it passes that • 1502 XON op-code to the next package and it exits the 'waiting for its own XON' state.

- If it receives an XON op-code with the Package ID equal to its own, it sends an XON frame on the NC-SI when it receives the TOKEN op-code and exits the 'waiting for its own XON' state.
 - NOTE More than one XON op-code with the same Package ID may be received while waiting for the TOKEN and while sending the XON frame. These additional XON op-codes should be discarded.
- If a package originates an XON op-code but receives an XOFF op-code, it terminates its XON request so that it does not output an XON frame when it receives the TOKEN.
- 1511NOTEThis behavior should not occur because the Management Controller will be in the Pause state
at this point.
- A package that generated an XON op-code may receive its own XON op-code back while it has the TOKEN op-code. In this case, it may send a regular packet (Pass-through, command response, or AEN) to the Management Controller (if it has one to send), an XON frame, or both.

1516 **7.2.4 Bypass mode**

1506

1507

1508

1517 When the Network Controller package is in bypass mode, data received on the ARB_IN pin is redirected 1518 to the ARB_OUT pin within the specified clock delay. This way, arbitration can continue between other 1519 devices in the ring.

A package in bypass mode shall take no more than T10 REF_CLK times to forward data from the ARB_IN pin to the ARB_OUT pin. The transition in and out of bypass mode may result in a truncated op-code.

A Network Controller package enters into bypass mode immediately upon power up and transitions out of this mode after the Network Controller completes its startup/initialization sequence.

1525 **7.2.5 Hardware arbitration startup**

- 1526 Hardware arbitration startup works as follows:
- 1527 1) All the packages shall be in bypass mode within T_{pwrz} seconds of NC-SI power up.
- As each package is initialized, it shall continuously generate FLUSH op-codes with its own
 Package ID.
- 15303)The package then participates in the ARB_MSTR assignment process described in the1531following clause.

1532 **7.2.6 ARB_MSTR assignment**

- 1533 ARB_MSTR assignment works as follows:
- 15341)When a package receives a FLUSH op-code with a Package ID numerically smaller than its
own, it shall forward on the received FLUSH op-code. If the received FLUSH op-code's1536Package ID is numerically larger than the local Package ID, the package shall continue to send
its FLUSH op-code with its own Package ID. When a package receives a FLUSH op-code with
its own Package ID, it becomes the master of the ring (ARB_MSTR).
- 1539 2) The ARB_MSTR shall then send out IDLE op-codes until it receives an IDLE op-code.
- Upon receiving the IDLE op-code, the ARB_MSTR shall be considered to be in possession of the TOKEN op-code (see 7.2.3.1).
- 1542NOTEIf the package receives a FLUSH op-code while it is in the middle of transmitting a packet onto1543NC-SI, it shall generate IDLE op-codes until the transmission is complete and then process the1544FLUSH op-code as described.

1545 **7.2.7 Token timeout mechanism**

Each Network Controller package that supports hardware-based arbitration control shall implement a
timeout mechanism in case the TOKEN op-code is not received. When a package has a packet to send, it
starts its timer. If it does not receive a TOKEN prior to the TOKEN timeout, the package shall send a
FLUSH op-code. This restarts the arbitration process.

The timer may be programmable depending on the number of packages in the ring. The timeout value is
designed to accommodate up to four packages, each sending the largest packet (1536 bytes) plus
possible XON or XOFF frame transmission and op-code processing time. The timeout shall be no fewer
than T8 cycles of the REF_CLK.

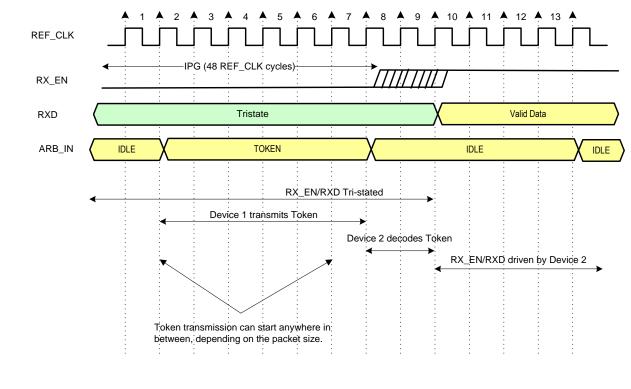

1554 **7.2.8 Timing considerations**

1555 The ARB_OUT and ARB_IN pins shall follow the timing specifications outlined in Clause 10.

1556 To improve the efficiency of the multi-drop NC-SI, TOKEN op-code generation may overlap the Inter

1557 Packet Gap (IPG) defined by the 802.3 specification, as shown in Figure 13. The TOKEN op-code shall

1558 be sent no earlier than the last T13 REF_CLK cycles of the IPG.

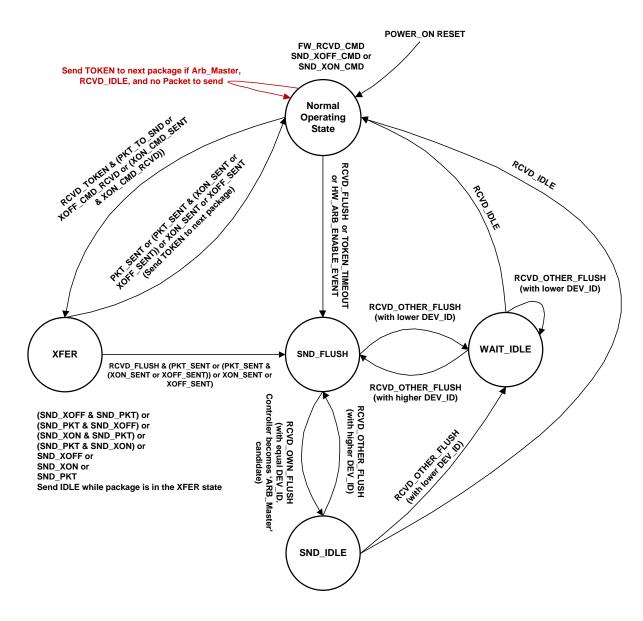

1560

1559

Figure 13 – Example TOKEN to transmit relationship

1561 **7.2.9 Example hardware arbitration state machine**

The state machine diagram shown in Figure 14 is provided as a guideline to help illustrate the startup process and op-code operations described in the preceding clauses.

1564

1565

Figure 14 – Hardware arbitration state machine

1566 The states and events shown in Figure 14 are described in Table 6 and Table 7, respectively.

1567

Table 6 – Hardware arbitration states

State	Action	
Normal Operating State	This state is the normal operating state for hardware arbitration. The following actions happen in this state:	
	• FW_RCVD_CMD: Forward received command. As op-codes are received and acted upon, the resulting op-code is sent to the next package. For example, the TOKEN op-code is received and no packet data is available to send, so the TOKEN op-code is sent to the next package in the ring.	
	 SND_XOFF_CMD: Send the XOFF op-code to the next package. This action happens when the specific conditions are met as described in 7.2.3. 	
	 SND_XON_CMD: Send the XON op-code to the next package. This action happens when the specific conditions are met as described in 7.2.3. 	
	 If the Network Controller is ARB_Master, it generates the TOKEN op-code upon receiving an IDLE op-code at the end of the FLUSH process. 	
	The RXD lines will be in a high-impedance condition in this state.	
XFER	In this state, data is sent on the RXD lines. This data will be a Pass-through packet, response packet, XON (Pause Off) packet, XOFF (Pause On) packet, or AEN. (An XON or XOFF packet can be sent in addition to a Pass-through packet, response packet, or AEN.) IDLE op-codes are sent to the next package while the device is in the XFER state.	
	The following actions happen in this state:	
	 SND_XON: Transmit an XON frame (Pause Off) to the Management Controller. 	
	 SND_XOFF: Transmit an XOFF frame (Pause On) to the Management Controller. 	
	 SND_PKT: Transmit a Pass-through packet, response packet, or AEN to the Management Controller. 	
	 The TOKEN op-code is sent to the next package upon completion of the transfer. 	
SND_FLUSH	This state is the entry point for determining the ARB_Master among the packages. In this state, the FLUSH op-code is continuously sent. This state i exited upon receiving a FLUSH op-code that has a DEV_ID that is equal to c lower than the package's own DEV_ID.	
SND_IDLE	This is the final state for determining the ARB_Master, entered when a device's own FLUSH op-code is received. In this state, the IDLE op-code is continuously sent.	
WAIT_IDLE	This state is entered when a FLUSH command is received from another package with a lower Device ID. When an IDLE op-code is received, the ARB_Master has been determined and the device transitions to the Normal Operating State.	

Table 7 – Hardware arbitration events

Event	Description
RCVD_TOKEN	A TOKEN op-code was received or the arbitration was just completed and won by this package.
RCVD_IDLE	An IDLE op-code was received.
XOFF_SENT	The Pause On frame was sent on the RXD interface.
XON_SENT	The Pause Off frame was sent on the RXD interface.
PKT_TO_SND	The Network Controller package has a Pass-through packet, command response packet, XON (Pause Off) frame, XOFF (Pause On) frame, or AEN to send.
XON_CMD_RCVD	A package received an XON op-code with its own Package ID.
XOFF_CMD_RCVD	An XOFF op-code was received.
XON_CMD_SENT	A package sent an XON op-code with its own Package ID.
RCVD_FLUSH	A FLUSH op-code was received.
TOKEN_TIMEOUT	The timeout limit expired while waiting for a TOKEN op-code.
HW_ARB_ENABLE_EVENT	This event begins ARB_MSTR assignment. This event occurs just after the Network Controller package initializes or when hardware arbitration is re- enabled through the Select Package command.
RCVD_OTHER_FLUSH	A package received a FLUSH op-code with a Package ID other than its own.
RCVD_OWN_FLUSH	A package received a FLUSH op-code with a Package ID equal to its own.

1569 **7.3 Command-based arbitration**

1570 If hardware arbitration is not being used, the **Select Package** and **Deselect Package** commands shall be 1571 used to control which Network Controller package has the ability to transmit on the RXD lines. Because 1572 only one Network Controller package is allowed to transmit on the RXD lines, the Management Controller 1573 shall only have one package in the selected state at any given time. For more information, see 8.4.5 and 1574 8.4.7.

1575 8 Packet definitions

1576 This clause presents the formats of NC-SI packets and their relationship to frames used to transmit and 1577 receive those packets on NC-SI.

1578 8.1 NC-SI packet encapsulation

- 1579 The NC-SI is an Ethernet interface adhering to the standard <u>IEEE 802.3</u> Ethernet frame format. Whether 1580 or not the Network Controller accepts runt packets is unspecified.
- 1581 As shown in Figure 15, this L2, or data link layer, frame format encapsulates all NC-SI packets, including
- 1582 Pass-through, command, and response packets, as the L2 frame payload data by adding a 14-byte
- 1583 header to the front of the data and appending a 4-byte Frame Check Sequence (FCS) to the end.
- 1584 NC-SI Control Messages shall not include any VLAN tags. NC-SI Pass-through may include 802.1Q
 1585 VLAN tag.

1587

Figure 15 – Ethernet frame encapsulation of NC-SI packet data without VLAN tag

1588 8.1.1 Ethernet frame header

1589 The Management Controller shall format the 14-byte Ethernet frame header so that when it is received, it 1590 shall be formatted in the big-endian byte order shown in Table 8.

1591 Channels shall accept Pass-through packets that meet the <u>IEEE 802.3</u> frame requirements.

1592

Table 8 – Ethernet Header Format

	Bits			
Bytes	3124	2316	1508	0700
0003	$DA_5=OxFF$	$DA_4=OxFF$	$DA_3=OxFF$	$DA_2=OxFF$
0407	$DA_1 = OxFF$	DA ₀ = 0xFF	SA₅	SA4
0811	SA ₃	SA ₂	SA ₁	SA ₀
1213	EtherType = 0x88F8 (DMTF NC-SI)			

1593 8.1.1.1 Destination Address (DA)

1594 Bytes 0–5 of the header represent bytes 5–0 of the Ethernet Destination Address field of an L2 header.

1595The channel is not assigned a specific MAC address and the contents of this field are not interpreted as a MAC1596address by the Management Controller or the Network Controller. However, the DA field in all NC-SI Control1597Messages shall be set to the broadcast address (FF:FF:FF:FF:FF:FF) for consistency.

1598 If the Network Controller receives a Control Message with a Destination Address other than FF:FF:FF:FF:FF;
 1599 the Network Controller may elect to accept the packet, drop it, or return a response packet with an error
 1600 response/reason code.

1601 8.1.1.2 Source Address (SA)

Bytes 6–11 of the header represent bytes 5–0 of the Ethernet Source Address field of the Ethernet header. The contents of this field may be set to any value. The Network Controller may use

1604 FF:FF:FF:FF:FF as the source address for NC-SI Control Messages that it generates.

1605 **8.1.1.3 EtherType**

1606 The final two bytes of the header, bytes 12..13, represent bytes 1..0 of the EtherType field of the Ethernet

1607 header. For NC-SI Control Messages, this field shall be set to a fixed value of 0x88F8 as assigned to the

1608 NC-SI by the IEEE. This value allows NC-SI Control Messages to be differentiated from other packets in 1609 the overall packet stream.

1610 8.1.2 Frame Check Sequence

1611 The Frame Check Sequence (FCS) shall be added at the end of the frame to provide detection of 1612 corruption of the frame. Any frame with an invalid FCS shall be discarded.

1613 **8.1.3 Data length**

1614

1.5 Data length

NC-SI Commands, Responses, and AENs do not carry any VLAN tag. NC-SI Commands, Responses
and AENs shall have a payload data length between 46 and 1500 octets (bytes). This is in compliance
with the 802.3 specification. This means that the length of Ethernet frame shown in Figure 15 is between
64 octets (for a payload of 46 octets) and 1518 octets (for a payload with 1500 octets).

1619

Pass-through packets also follow the 802.3 specification. The maximum payload size is 1500 octets; the minimum payload size shall be 42 octets when 802.1Q (VLAN) tag is present and 46 octets when the 802.1Q tag is not present. The Layer-2 Ethernet frame for a 802.1Q tagged frame shall be between 64 octets (for a payload of 42 octets) and 1522 octets (for a payload with 1500 octets). For Pass-through packets that are not 802.1Q tagged, the minimum Layer-2 Ethernet frame size is 64 octets (for a payload of 46 octets) and the maximum Layer-2 Ethernet frame size is 1518 octets (for a payload with 1500 octets).

1627 8.2 Control Message data structure

1628 Each NC-SI Control Message is made up of a 16-byte packet header and a payload section whose length 1629 is specific to the packet type.

1630 8.2.1 Control Message header

1631 The 16-byte Control Message header is used in command, response, and AEN packets, and contains 1632 data values intended to allow the packet to be identified, validated, and processed. The packet header is 1633 in big-endian byte order, as shown in Table 9.

1634

Table 9 – Control Message header format

	Bits			
Bytes	3124	2316	1508	0700
0003	MC ID	Header Revision	Reserved	IID
0407	Control Message Type	Ch. ID	Flags	Payload Length
0811	Reserved			
1215	Reserved			

1635 8.2.1.1 Management Controller ID

1636 In Control Messages, this 1-byte field identifies the Management Controller issuing the packet. For this 1637 version of the specification, Management Controllers should set this field to 0×00 (zero). This implies that 1638 only one management controller is supported for accessing the NC via NC-SI at any given time, Network 1639 Controllers responding to command packets should copy the Management Controller ID field from the 1640 command packet header into the response packet header. For AEN packets, this field should be copied 1641 from the parameter that was set using the AEN Enable command.

1642 **8.2.1.2 Header revision**

1643 This 1-byte field identifies the version of the Control Message header in use by the sender. For this 1644 version of the specification, the header revision is 0x01.

1645 8.2.1.3 Instance ID (IID)

1646 This 1-byte field contains the IID of the command and associated response. The Network Controller can 1647 use it to differentiate retried commands from new instances of commands. The Management Controller 1648 can use this value to match a received response to the previously sent command. For more information, 1649 see 6.3.1.1.

1650 8.2.1.4 Control Message type

1651 This 1-byte field contains the Identifier that is used to identify specific commands and responses, and to 1652 differentiate AENs from responses. Each NC-SI command is assigned a unique 7-bit command type 1653 value in the range $0 \times 00..0 \times 60$. The proper response type for each command type is formed by setting 1654 the most significant bit (bit 7) in the original 1-byte command value. This allows for a one-to-one 1655 correspondence between 96 unique response types and 96 unique command types.

1656 **8.2.1.5 Channel ID**

1657 This 1-byte field contains the Network Controller Channel Identifier. The Management Controller shall set 1658 this value to specify the package and internal channel ID for which the command is intended.

In a multi-drop configuration, all commands are received by all NC-SI Network Controllers present in the
configuration. The Channel ID is used by each receiving Network Controller to determine if it is the
intended recipient of the command. In Responses and AENs, this field carries the ID of the channel from
which the response of AEN was issued.

1663 8.2.1.6 Payload length

1664 This 12-bit field contains the length, in bytes, of any payload data present in the command or response 1665 frame following the NC-SI packet header. This value does not include the length of the NC-SI Control 1666 Message Header, the checksum value, or any padding that might be present.

1667 **8.2.1.7 Flags**

Bit 0: Poll Indication: If this bit is set, it indicates that this is a polling on a previous command that was responded with a "Delayed Response" response code. This bit is relevant only for commands and not for responses or AENs.

1671 Bits 7:1: Reserved

1672 8.2.1.8 Reserved

1673 These fields are reserved for future use and should be written as zeros and ignored when read.

1674 8.2.2 Control Message payload

1675 The NC-SI packet payload may contain zero or more defined data values depending on whether the 1676 packet is a command or response packet, and on the specific type. The NC-SI packet payload is always 1677 formatted in big-endian byte order, as shown in Table 10.

Table 10 – Generic example of Control Message payload

	Bits			
Bytes	3124	2316	1508	0700
0003	Data0 ₃	Data0 ₂	Data0₁	Data0 ₀
0407	Data17	Data1 ₆	Data1₅	Data1 ₄
0811	Data1 ₃	Data1 ₂	Data1₁	Data1 ₀
	DataN-1 ₄	DataN-13	DataN-12	DataN-11
	DataN-1 ₀ Payload Pad (as required)			
	2s Complement Checksum Compensation			
	Ethernet Packet Pad (as required)			

1679 8.2.2.1 Data

As shown in Table 10, the bytes following the NC-SI packet header may contain payload data fields of varying sizes, and which may be aligned or require padding. In the case where data is defined in the payload, all data-field byte layouts (Data0–Data-1) shall use big-endian byte ordering with the most significant byte of the field in the lowest addressed byte position (that is, coming first).

1684 **8.2.2.2 Payload pad**

1685 If the payload is present and does not end on a 32-bit boundary, one to three padding bytes equal to 1686 0×00 shall be present to align the checksum field to a 32-bit boundary.

1687 **8.2.2.3 2's Complement checksum compensation**

This 4-byte field contains the 32-bit checksum compensation value that may be included in each command and response packet by the sender of the packet. When it is implemented, the checksum compensation shall be computed as the 2's complement of the checksum, which shall be computed as the 32-bit unsigned sum of the NC-SI packet header and NC-SI packet payload interpreted as a series of 1692 16-bit unsigned integer values. A packet receiver supporting packet checksum verification shall use the checksum compensation value to verify packet data integrity by computing the 32-bit checksum described above, adding to it the checksum compensation value from the packet, and verifying that the result is 0.

1695 Verification of non-zero NC-SI packet checksum values is optional. An implementation may elect to 1696 generate the checksums and may elect to verify checksums that it receives. The checksum field is 1697 generated and handled according to the following rules:

- A checksum field value of all zeros specifies that a header checksum is not being provided for the NC-SI Control Message, and that the checksum field value shall be ignored when processing the packet.
- If the originator of an NC-SI Control Message is not generating a checksum, the originator shall use a value of all zeros for the header checksum field.
- If a non-zero checksum field is generated for an NC-SI Control Message, that header checksum field value shall be calculated using the specified algorithm.
- All receivers of NC-SI Control Messages shall accept packets with all zeros as the checksum value (provided that other fields and the CRC are correct).

- The receiver of an NC-SI Control Message may reject (silently discard) a packet that has an incorrect non-zero checksum.
- The receiver of an NC-SI Control Message may ignore any non-zero checksums that it receives and accept the packet, even if the checksum value is incorrect (that is, an implementation is not required to verify the checksum field).
- A controller that generates checksums is not required to verify checksums that it receives.
- A controller that verifies checksums is not required to generate checksums for NC-SI Control
 Messages that it originates.

1715 8.2.2.4 Ethernet packet pad

Per IEEE 802.3, all Ethernet frames shall be at least 64 bytes in length, from the DA through and
including FCS. For NC-SI packets, this requirement applies to the Ethernet header and payload, which
includes the NC-SI Control Message header and payload. Most NC-SI Control Messages are less than
the minimum Ethernet frame payload size of 46 bytes in length and require padding to comply with
IEEE 802.3.

1721 8.2.3 Command packet Payload

1722 Command packets have no common fixed payload format.

1723 8.2.4 Response packet payload

Unlike command packets that do not necessarily contain payload data, all response packets carry at least
a 4-byte payload. This default payload carries the response codes and reason codes (described in
8.2.4.1) that provide status on the outcome of processing the originating command packet, and is present
in all response packet payload definitions.

The default payload occupies bytes 00..03 of the response packet payload, with any additional
response-packet-specific payload defined to follow starting on the next word. All response packet payload
fields are defined with big-endian byte ordering, as shown in Table 11.

1731

Table 11 – Generic example of response packet payload format

	Bits			
Bytes	3124	2316	1508	0700
0003	Respon	se Code	Reaso	n Code
	DataN-1 ₄	DataN-13	DataN-1 ₂	DataN-11
	DataN-1 ₀ Word Pad (as required)			1)
	2s Complement Checksum Compensation			
	Ethernet Packet Pad (as required)			

1732 8.2.4.1 Response Packet in case of Delayed Response Code

1733 If a response includes a "Delayed Response" Code, then the response doesn't contain the payload of the

original response, The Delayed Response shall contain a payload of a single word (uint16) including the

1735 recommended next polling time in milliseconds. If no polling time estimate is available, then the

recommended next polling time shall be set to 0x0000.

1737 8.2.5 Response codes and reason codes

- 1738 Response codes and reason codes are status values that are returned in the responses to NC-SI
- commands. The response code values provide a general categorization of the status being returned. The
 reason code values provide additional detail related to a particular response code.

1741 8.2.5.1 General

1742 Response codes and reason codes are divided into numeric ranges that distinguish whether the values
1743 represent standard codes that are defined in this specification or are vendor/OEM-specific values that are
1744 defined by the vendor of the controller.

1745 The response code is a 2-byte field where values from 0×00 through $0 \times 7F$ are reserved for definition by 1746 this specification. Values from 0×80 through $0 \times FF$ are vendor/OEM-specific codes that are defined by the 1747 vendor of the controller.

1748 The reason code is a 2-byte field. The ranges of values are defined in Table 12.

1749

Table	12 –	Reason	code	ranges
1 4 10 10		11040011	0040	rangee

MS-byte	LS-byte	Description
	0x00-0x7F	Standard generic reason codes
00h		This range of values for the lower byte is used for reason codes that are not specific to a particular command but can be used as reason codes in responses for any command. The values in this range are reserved for definition by this specification.
0011	0x80-0xFF	Vendor/OEM generic reason codes
specific to a particular command but		This range of values for the lower byte is used for reason codes that are not specific to a particular command but can be used as reason codes in responses for any command. Values in this range are defined by the vendor of the controller.
Command	0x00-0x7F	Standard command-specific reason codes
Number		This range of values for the lower byte is used for reason codes that are
Note: This means that Command		specific to a particular command. The upper byte holds the value of the command for which the reason code is defined. The values in this range are reserved for definition by this specification.
Number 00	0x80-0xFF	Vendor/OEM command-specific reason codes
cannot have any command- specific reason codes.		This range of values for the lower byte is used for reason codes that are specific to a particular command. The upper byte holds the value of the command for which the reason code is defined. Values in this range are defined by the vendor of the controller.

1750 **8.2.5.2 Response code and reason code values**

1751 The standard response code values are defined in Table 13, and the standard reason code values are 1752 defined in Table 14. Command-specific values, if any, are defined in the clauses that describe the 1753 response data for the command. Unless otherwise specified, the standard reason codes may be used in 1754 combination with any response code. There are scenarios where multiple combinations of response and 1755 reason code values are valid. Unless otherwise specified, an implementation may return any valid 1756 combination of response and reason code values for the condition.

Table 13 – Standard response code values

Value	Description	Comment
0x0000	Command Completed	Returned for a successful command completion. When this response code is returned, the reason code shall be 0x0000 as described in Table 14 unless a more informative reason code is appropriate such as 0x0E08 meaning <u>MAC Address is zero</u> .
0x0001	Command Failed	Returned to report that a valid command could not be processed or failed to complete correctly
0x0002	Command Unavailable	Returned to report that a command is temporarily unavailable for execution because the controller is in a transient state or busy condition
0x0003	Command Unsupported	Returned to report that a command is not supported by the implementation. The reason code "Unknown / Unsupported Command Type should be returned along with this response code for all unsupported commands.
0x0004	Delayed Response	Returned to report that the command was accepted, and the NC started to handle it, but it cannot respond within T5 seconds with a final answer.
		When this response code is provided, the reason code shall be 0x0000
0x8000-0xFFFF	Vendor/OEM-specific	Response codes defined by the vendor of the controller

1758

Table 14 – Standard Reason Code Values

Value	Description	Comment
0x0000	No Error/No Reason Code	When used with the Command Completed response code, indicates that the command completed normally. Otherwise this value indicates that no additional reason code information is being provided.
0x0001	Interface Initialization Required	Returned for all commands except Select/Deselect Package commands when the channel is in the Initial State, until the channel receives a Clear Initial State command
0x0002	Parameter Is Invalid, Unsupported, or Out-of- Range	Returned when a received parameter value is outside of the acceptable values for that parameter
0x0003	Channel Not Ready	May be returned when the channel is in a transient state in which it is unable to process commands normally
0x0004	Package Not Ready	May be returned when the package and channels within the package are in a transient state in which normal command processing cannot be done
0x0005	Invalid payload length	The payload length in the command is incorrect for the given command
0x0006	Information not available	Returned when the channel is unable to provide response data to a valid supported command.

Value	Description	Comment
0x7fff	Unknown / Unsupported Command Type	Returned when the command type is unknown or unsupported. This reason code shall only be used when the response code is 0x0003 (Command Unsupported) as described in Table 13.
0x8000-0xFFFF	OEM Reason Code	Vendor-specific reason code defined by the vendor of the controller

1759 8.2.6 AEN packet format

AEN packets shall follow the general packet format of Control Messages, with the IID field set to 0
because, by definition, the Management Controller does not send a response packet to acknowledge an
AEN packet. The Control Message Type field shall have the value 0xFF. The originating Network
Controller shall fill in the Channel ID (Ch. ID) field with its own ID to identify itself as the source of
notification. Currently, three AEN types are defined in the AEN Type field. Table 15 represents the
general AEN packet format.

1766

1773 8.3 Control Message type definitions

1774 Command packet types are in the range of 0x00 to 0x7F. Table 18 describes each command, its
1775 corresponding response, and the type value for each. Table 18 includes commands addressed to either a
1776 package or a channel. The commands addressed to a package are highlighted with gray background.
1777 PLDM and OEM-specific commands carried over NC-SI may be package specific or channel specific or
1778 both.

Mandatory (M), Optional (O), and Conditional (C) refer to command support requirements for the NetworkController.

1781

Table 18 – Command and response types

Command Type	Command Name	Description	Response Type	Command Support Requirement
0x00	Clear Initial State	Used by the Management Controller to acknowledge that the Network Controller is in the Initial State	0x80	М
0x01	Select Package	Used to explicitly select a controller package to transmit packets through the NC-SI interface	0x81	М
0x02	Deselect Package	Used to explicitly instruct the controller package to stop transmitting packets through the NC-SI interface	0x82	М
0x03	Enable Channel	Used to enable the NC-SI channel and to cause the forwarding of bidirectional Management Controller packets to start	0x83	М
0x04	Disable Channel	Used to disable the NC-SI channel and to cause the forwarding of bidirectional Management Controller packets to cease	0x84	М

Command Type	Command Name	Description	Response Type	Command Support Requirement
0x05	Reset Channel	Used to synchronously put the Network Controller back to the Initial State	0x85	М
0x06	Enable Channel Network TX	Used to explicitly enable the channel to transmit Pass-through packets onto the network	0x86	М
0x07	Disable Channel Network TX	Used to explicitly disable the channel from transmitting Pass-through packets onto the network	0x87	М
0x08	AEN Enable	Used to control generating AENs	0x88	С
0x09	Set Link	Used during OS absence to force link settings, or to return to auto-negotiation mode	0x89	М

1791 8.4.3 Clear Initial State command (0x00)

The Clear Initial State command provides the mechanism for the Management Controller to acknowledge that it considers a channel to be in the Initial State (typically because the Management Controller received an "Interface Initialization Required" reason code) and to direct the Network Controller to start accepting commands for initializing or recovering the NC-SI operation. When in the Initial State, the Network Controller shall return the "Interface Initialization Required" reason code for all commands until it receives the Clear Initial State command.

1798 If the channel is in the Initial State when it receives the Clear Initial State command, the command shall 1799 cause the Network Controller to stop returning the "Interface Initialization Required" reason code. The

channel shall also treat any subsequently received instance ID numbers as IDs for new commandinstances, not retries.

1802 If the channel is not in the Initial State when it receives this command, it shall treat any subsequently 1803 received instance ID numbers as IDs for new command instances, not retries.

1804 Table 21 illustrates the packet format of the Clear Initial State command.

2445	Pad			

1809 8.4.5 Select Package command (0x01)

1810 A package is considered to be "selected" when its NC-SI output buffers are allowed to transmit packets 1811 through the NC-SI interface. Conversely, a package is "deselected" when it is not allowed to transmit

1812 packets through the NC-SI interface.

1813 The Select Package command provides a way for a Management Controller to explicitly take a package

1814 out of the deselected state and to control whether hardware arbitration is enabled for the package.

1815 (Similarly, the Deselect Package command allows a Management Controller to explicitly deselect a 1816 package.)

1817 The NC-SI package in the Network Controller shall also become selected if the package receives any 1818 other NC-SI command that is directed to the package or to a channel within the package.

1819 The Select Package command is addressed to the package, rather than to a particular channel (that is,

the command is sent with a Channel ID where the Package ID subfield matches the ID of the intended package and the Internal Channel ID subfield is set to $0 \times 1F$).

1822 More than one package can be in the selected state simultaneously if hardware arbitration is used

1823 between the selected packages and is active. The hardware arbitration logic ensures that buffer conflicts 1824 will not occur between selected packages.

- 1825 If hardware arbitration is not active or is not used for a given package, only one package shall be selected
- at a time. To switch between packages, the Deselect Package command is used by the Management
 Controller to put the presently selected package into the deselected state before another package is
- 1828 selected.
- 1829 A package shall stay in the selected state until it receives a Deselect Package command, unless an 1830 internal condition causes all internal channels to enter the Initial State.
- A package that is not using hardware arbitration may leave its output buffers enabled for the time that it is
 selected, or it may place its output buffers into the high-impedance state between transmitting packets
 through the NC-SI interface. (Temporarily placing the output buffers into the high-impedance state is not
 the same as entering the deselected state.)
- For Type A integrated controllers: Because the bus buffers are separately controlled, a separate Select
 Package command needs to be sent to each Package ID in the controller that is to be enabled to transmit
 through the NC-SI interface. If the internal packages do not support hardware arbitration, only one
 package shall be selected at a time; otherwise, a bus conflict will occur.
- For Type S single channel, and Types B and C integrated controllers: A single set of bus buffers exists for the package. Sending a Select Package command selects the entire package and enables all channels within the package to transmit through the NC-SI interface. (Whether a particular channel in a selected package starts transmitting Pass-through and AEN packets depends on whether that channel was enabled or disabled using the Enable or Disable Channel commands and whether the package may have had packets queued up for transmission.)
- Table 23 illustrates the packet format of the Select Package command. Table 24 illustrates the disablebyte for hardware arbitration.
- 1847

Table 23 – Select Package command packet format

	Bits

1848

Table 24 – Features Control byte

Bits	Description
	0b = Hardware arbitration between packages is enabled.
0	1b = Disable hardware arbitration. Disabling hardware arbitration causes the package's arbitration logic to enter or remain in bypass mode.
	In the case that the Network Controller does not support hardware arbitration, this bit is ignored; the Network Controller shall not return an error if the Select Package command can otherwise be successfully processed.
	Delayed Response Enable:
1	0b = NC is not allowed to use the "Delayed Response" response code
	1b = NC is allowed to use the "Delayed Response" response code
72	Reserved

1849 8.4.6 Select package response (0x81)

- 1850 Currently no command-specific reason code is identified for this response (see Table 25).
- 1851

1852 8.4.7 Deselect Package command (0x02)

1853The Deselect Package command directs the controller package to stop transmitting packets through the1854NC-SI interface and to place the output buffers for the package into the high-impedance state.

1855 The Deselect Package command is addressed to the package, rather than to a particular channel (that is, 1856 the command is sent with a Channel ID where the Package ID subfield matches the ID of the intended 1857 package and the Internal Channel ID subfield is set to $0 \times 1F$).

1858 The controller package enters the deselected state after it has transmitted the response to the Deselect 1859 Package command and placed its buffers into the high-impedance state. The controller shall place its 1860 outputs into the high-impedance state within the Package Deselect to Hi-Z Interval (T1). (This interval 1861 gives the controller being deselected time to turn off its electrical output buffers after sending the 1862 response to the Deselect Package command.)

1863 If hardware arbitration is not supported or used, the Management Controller should wait for the Package
 1864 Deselect to Hi-Z Interval (T1) to expire before selecting another controller.

For Type A integrated controllers: Because the bus buffers are separately controlled, putting the overall
 controller package into the high-impedance state requires sending separate Deselect Package
 commands to each Package ID in the overall package.

For Type S single channel, and Types B and C integrated controllers: A single set of bus buffers exists for
 the package. Sending a Deselect Package command deselects the entire NC-SI package and prevents
 all channels within the package from transmitting through the NC-SI interface.

1871 Table 26 illustrates the packet format of the Deselect Package command.

1872

1886 **8.4.11 Disable Channel command (0x04)**

1887 The Disable Channel command allows the Management Controller to disable the flow of packets, 1888 including Pass-through and AEN, to the Management Controller.

A Network Controller implementation is not required to flush pending packets from its RX Queues when a
 channel becomes disabled. If queuing is subsequently disabled for a channel, it is possible that a number
 of packets from the disabled channel could still be pending in the RX Queues. These packets may
 continue to be transmitted through the NC-SI interface until the RX Queues are emptied of those packets.
 The Management Controller should be aware that it may receive a number of packets from the channel

1894 before receiving the response to the Disable Channel command.

The 1-bit Allow Link Down (ALD) field can be used by the Management Controller to indicate that the link
corresponding to the specified channel is not required after the channel is disabled. The Network
Controller is allowed to take down the external network physical link if no other functionality (for example,
host OS or WoL [Wake-on-LAN]) is active.

- 1899 Possible values for the 1-bit ALD field are as follows:
- 1900 0b = Keep link up (establish and/or keep a link established) while channel is disabled
- 1901 1b = Allow link to be taken down while channel is disabled
- 1902 Table 30 illustrates the packet format of the Disable Channel command.
- 1903

1910 8.4.13 Reset Channel command (0x05)

1911 The Reset Channel command allows the Management Controller to put the channel into the Initial State.

1912 Packet transmission is not required to stop until the Reset Channel response has been sent. Thus, the

1913 Management Controller should be aware that it may receive a number of packets from the channel before 1914 receiving the response to the Reset Channel command.

1915 Table 32 illustrates the packet format of the Reset Channel command.

1916

1920 8.4.15 Enable Channel Network TX command (0x06)

The Enable Channel Network TX command shall enable the channel to transmit Pass-through packets
onto the network. After network transmission is enabled, this setting shall remain enabled until a Disable
Channel Network TX command is received or the channel enters the Initial State.

1924 The intention of this command is to control which Network Controller ports are allowed to transmit to the 1925 external network. The Network Controller compares the source MAC address in outgoing Pass-through 1926 packets to the unicast MAC address(es) configured using the Set MAC Address command. If a match 1927 exists, the packet is transmitted to the network.

1928 Table 34 illustrates the packet format of the Enable Channel Network TX command.

1929

1945 8.4.19 AEN Enable command (0x08)

1946 Network Controller implementations shall support this command on the condition that the Network

1947 Controller generates one or more standard AENs. The AEN Enable command enables and disables the
 1948 different standard AENs supported by the Network Controller. The Network Controller shall copy the AEN
 1949 MC ID field from the AEN Enable command into the MC ID field in every subsequent AEN sent to the
 1950 Management Controller.

1951 For more information, see 8.5 ("AEN packet formats") and 8.2.1.1 ("Management Controller ID").

1952 Control of transport-specific AENs is outside the scope of this specification, and should be defined by the 1953 particular transport binding specifications.

- 1954 Table 38 illustrates the packet format of the AEN Enable command.

1961 **8.4.21 Set Link command (0x09)**

The Set Link command may be used by the Management Controller to configure the external network interface associated with the channel by using the provided settings. Upon receiving this command, while the host NC driver is not operational, the channel shall attempt to set the link to the configuration specified by the parameters. Upon successful completion of this command, link settings specified in the command should be used by the network controller as long as the host NC driver does not overwrite the link settings.

In the absence of an operational host NC driver, the NC should attempt to make the requested link state
change even if it requires the NC to drop the current link. The channel shall send a response packet to
the Management Controller within the required response time. However, the requested link state changes
may take an unspecified amount of time to complete.

1972 The actual link settings are controlled by the host NC driver when it is operational. When the host NC 1973 driver is operational, link settings specified by the MC using the Set Link command may be overwritten by 1974 the host NC driver. The link settings are not restored by the NC if the host NC driver becomes non-

1975 operational.

1976 Table 41 illustrates the packet format of the Set Link command.

1982 **8.4.22 Set Link Response (0x89)**

1983 The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Set Link 1984 command and send a response (see Table 44). In the presence of an operational Host NC driver, the NC 1985 should not attempt to make link state changes and should send a response with reason code 0x1 (Set 1986 Link Host OS/ Driver Conflict).

1987 If the Auto Negotiation field is set, the NC should ignore Link Speed Selection and Duplex Setting fields 1988 that are not supported by the NC.

1989

2002 Table 48 describes the Link Status bit definitions.

Table 48 – Link Status field bit definitions

Bit Position	Field Description	Value Description
00	Link Flag	0b = Link is down 1b = Link is up This field is mandatory. NOTE If the IEEE 802.3az (EEE) is enabled on the link, Low Power Idle (LPI) state shall not be interpreted as "Link is down".
0401	Speed and duplex	 0x0 = Auto-negotiate not complete [per IEEE 802.3], or SerDes Flag = 1b, or no Highest Common Denominator (HCD) from the following options (0x1 through 0xF) was found. 0x1 = 10BASE-T half-duplex 0x2 = 10BASE-T full-duplex 0x3 = 100BASE-TX half-duplex 0x4 = 100BASE-TX half-duplex 0x5 = 100BASE-TX full-duplex 0x6 = 1000BASE-T full-duplex 0x7 = 1000BASE-T half-duplex 0x8 = 10G-BASE-T support or 10 Gbps 0x9 = 20 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0) 0xA = 25 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0) 0xB = 40 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0) 0xC = 50 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0) 0xE = 2.5 Gbps (optional for NC-SI 1.1, Reserved for NC-SI 1.0) 0xF = Use values defined in Enhanced Speed and Duplex field starting at bit 24 (optional for NC-SI 1.1, Reserved for NC-SI 1.0) 0xF = Use values defined in Enhanced Speed and Duplex field starting at bit 24 (optional for NC-SI 1.1, Reserved for NC-SI 1.0) NOTE For the physical medium and/or speed/duplex not listed above, the closest speed and duplex option may be reported by the NC. This field should not be used to infer any media type information.
05	Auto Negotiate Flag	 1b = Auto-negotiation is enabled. This field always returns 0b if auto-negotiation is not supported, or not enabled.
		This field is mandatory if supported by the controller.
06	Auto Negotiate Complete	 1b = Auto-negotiation has completed. This includes if auto-negotiation was completed using Parallel Detection. Always returns 0b if auto-negotiation is not supported or is not enabled. This field is mandatory if the Auto Negotiate Flag is supported.

Bit Position	Field Description	Value Description
07	Parallel Detection Flag	1b = Link partner did not support auto-negotiation and parallel detection was used to get link.
		This field contains 0b if Parallel Detection was not used to obtain link.
08	Reserved	None
09	Link Partner Advertised	1b = Link Partner is 1000BASE-T full-duplex capable.
	Speed and Duplex 1000TFD	Valid when:
		SerDes Flag = 0b
		Auto-Negotiate Flag = 1b
		Auto-Negotiate Complete = 1b
		This field is mandatory.
10	Link Partner Advertised	1b = Link Partner is 1000BASE-T half-duplex capable.
	Speed and Duplex 1000THD	Valid when:
		SerDes Flag = 0b
		Auto-Negotiate Flag = 1b
		Auto-Negotiate Complete = 1b
		This field is mandatory.
11	Link Partner Advertised	1b = Link Partner is 100BASE-T4 capable.
	Speed 100T4	Valid when:
		SerDes Flag = 0b
		Auto-Negotiate Flag = 1b
		Auto-Negotiate Complete = 1b
		This field is mandatory.
12	Link Partner Advertised	1b = Link Partner is 100BASE-TX full-duplex capable.
	Speed and Duplex 100TXFD	Valid when:
		SerDes Flag = 0b
		Auto-Negotiate Flag = 1b
		Auto-Negotiate Complete = 1b
		This field is mandatory.
13	Link Partner Advertised	1b = Link Partner is 100BASE-TX half-duplex capable.
	Speed and Duplex 100TXHD	Valid when:
		SerDes Flag = 0b
		Auto-Negotiate Flag = 1b
		Auto-Negotiate Complete = 1b
		This field is mandatory.

Bit Position	Field Description	Value Description
14	Link Partner Advertised	1b = Link Partner is 10BASE-T full-duplex capable.
	Speed and Duplex 10TFD	Valid when:
		SerDes Flag = 0b
		Auto-Negotiate Flag = 1b
		Auto-Negotiate Complete = 1b
		This field is mandatory.
15	Link Partner Advertised	1b = Link Partner is 10BASE-T half-duplex capable.
	Speed and Duplex 10THD	Valid when:
		SerDes Flag = 0b
		Auto-Negotiate Flag = 1b
		Auto-Negotiate Complete = 1b
		This field is mandatory.
16	TX Flow Control Flag	0b = Transmission of Pause frames by the NC onto the external network interface is disabled.
		1b = Transmission of Pause frames by the NC onto the external network interface is enabled.
		This field is mandatory.

Table 51 describes the reason code that is specific to the Get Link Status command.

2009

Table 51 – Get Link Status command-specific reason code

Value	Description	Comment	
0x0A06	Link Command Failed- Hardware Access Error	Returned when PHY R/W access fails to complete normally while executing the Set Link or Get Link Status command	

2010 **8.4.25 Set VLAN Filter command (0x0B)**

The Set VLAN Filter command is used by the Management Controller to program one or more VLAN IDs that are used for VLAN filtering.

2013 Incoming packets that match both a VLAN ID filter and a MAC address filter are forwarded to the

2014 Management Controller. Other packets may be dropped based on the VLAN filtering mode per the Enable 2015 VLAN command.

2016 The quantity of each filter type that is supported by the channel can be discovered by means of the Get

2017 Capabilities command. Up to 15 filters can be supported per channel. A Network Controller

2018 implementation shall support at least one VLAN filter per channel.

To configure a VLAN filter, the Management Controller issues a Set VLAN Filter command with the Filter Selector field indicating which filter is to be configured, the VLAN ID field set to the VLAN TAG values to

be used by the filter, and the Enable field set to either enable or disable the selected filter.

2022 The VLAN-related fields are specified per IEEE 802.1q. When VLAN Tagging is used, the packet includes a Tag Protocol Identifier (TPID) field and VLAN Tag fields, as shown in Table 52.

2023

2024

Table 52 – IEEE 802.1q VLAN Fields	
------------------------------------	--

Field	Size	Description
ТРІ	2 bytes	Tag Protocol Identifier
		= 8100h
VLAN TAG – user priority	3 bits	User Priority (typical value = 000b)
VLAN TAG – CFI	1 bit	Canonical Format Indicator = 0b
VLAN TAG – VLAN ID	12 bits	Zeros = no VLAN

2025 When checking VLAN field values, the Network Controller shall match against the enabled VLAN Tag Filter values that were configured with the Set VLAN Filter command. The Network Controller shall also 2026 2027 match on the TPI value of 8100h, as specified by IEEE 802.1q. Matching against the User Priority/CFI 2028 bits is optional. An implementation may elect to ignore the setting of those fields.

2029 Table 53 illustrates the packet format of the Set VLAN Filter command.

2063 8.4.31 Set MAC Address command (0x0E)

- The Set MAC Address command is used by the Management Controller to program the channel's unicast or multicast MAC address filters.
- The channel supports one or more "perfect match" MAC address filters that are used to selectively forward inbound frames to the Management Controller. Assuming that a packet passes any VLAN filtering that may be active, it will be forwarded to the Management Controller if its 48-bit destination MAC address exactly matches an active MAC address filter.
- 2070 MAC address filters may be configured as unicast or multicast addresses, depending on the capability of 2071 the channel. The channel may implement three distinct types of filter:
- Unicast filters support exact matching on 48-bit unicast MAC addresses (AT = 0x0 only).
- **Multicast filters** support exact matching on 48-bit multicast MAC addresses (AT = 0x1 only).
- **Mixed filters** support matching on both unicast and multicast MAC addresses. (AT=0x0 or AT=0x1)
- The number of each type of filter that is supported by the channel can be discovered by means of the Get Capabilities command. The channel shall support at least one unicast address filter or one mixed filter, so that at least one unicast MAC address filter may be configured on the channel. Support for any combination of unicast, multicast, or mixed filters beyond this basic requirement is vendor specific. The total number of all filters shall be less than or equal to 8.

To configure an address filter, the Management Controller issues a Set MAC Address command with the
 Address Type field indicating the type of address to be programmed (unicast or multicast) and the MAC
 Address Num field indicating the specific filter to be programmed.

Filters are addressed using a 1-based index ordered over the unicast, multicast, and mixed filters reported by means of the Get Capabilities command. For example, if the interface reports four unicast filters, two multicast filters, and two mixed filters, then MAC Address numbers 1 through 4 refer to the interface's unicast filters, 5 and 6 refer to the multicast filters, and 7 and 8 refer to the mixed filters. Similarly, if the interface reports two unicast filters, no multicast filters, and six mixed filters, then MAC address numbers 1 and 2 refer to the unicast filters, and 3 through 8 refer to the mixed filters.

The filter type of the filter to be programmed (unicast, multicast, or mixed) shall be compatible with the Address Type being programmed. For example, programming a mixed filter to a unicast address is allowed, but programming a multicast filter to a unicast address is an error.

The Enable field determines whether the indicated filter is to be enabled or disabled. When a filter is programmed to be enabled, the filter is loaded with the 48-bit MAC address in the MAC Address field of the command, and the channel enables forwarding of frames that match the configured address. If the specified filter was already enabled, it is updated with the new address provided.

2097 When a filter is programmed to be disabled, the contents of the MAC Address field are ignored. Any 2098 previous MAC address programmed in the filter is discarded and the channel no longer uses this filter in 2099 its packet-forwarding function.

2100 Only unicast MAC addresses, specified with AT set to 0x0, should be used in source MAC address 2101 checking and for determining the NC-SI channel for Pass-through transmit traffic.

2102 Table 63 illustrates the packet format of the Set MAC Address command.

2103

Table 63 – Set MAC	Address	command	packet format

2115 8.4.33 Enable Broadcast Filter command (0x10)

2116 The Enable Broadcast Filter command allows the Management Controller to control the forwarding of

2117 broadcast frames to the Management Controller. The channel, upon receiving and processing this

command, shall filter all received broadcast frames based on the broadcast packet filtering settings 2118

specified in the payload. If no broadcast packet types are specified for forwarding, all broadcast packets 2119 shall be filtered out.

2120

2121 The Broadcast Packet Filter Settings field is used to specify those protocol-specific broadcast filters that 2122 should be activated. The channel indicates which broadcast filters it supports in the Broadcast Filter 2123 Capabilities field of the Get Capabilities Response frame defined in 8.4.46.

- 2124 Table 69 illustrates the packet format of the Enable Broadcast Filter command.

2126 Table 70 describes the Broadcast Packet Filter Settings field bit definitions.

2127

Table 70 – Broadcast Packet Filter Settings field

Bit Position	Field Description	Value Description
0	ARP Packets	1b = Forward this packet type to the Management Controller.0b = Filter out this packet type.
		For the purposes of this specification, an ARP broadcast packet is defined to be any packet that meets all of the following requirements:
		 The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF).
		• The EtherType field set to 0x0806.
		This field is mandatory.

Bit Position	Field Description	Value Description
1	DHCP Client Packets	1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.
		For the purposes of this filter, a DHCP client broadcast packet is defined to be any packet that meets all of the following requirements:
		 The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF;FF).
		• The EtherType field is set to 0x0800 (IPv4).
		The IP header's Protocol field is set to 17 (UDP).
		 The UDP destination port number is set to 68.
		This field is optional. If unsupported, broadcast DHCP client packets will be blocked when broadcast filtering is enabled. The value shall be set to 0 if unsupported.
2	DHCP Server Packets	1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.
		For the purposes of this filter, a DHCP server broadcast packet is defined to be any packet that meets all of the following requirements:
		 The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF:FF).
		• The EtherType field is set to 0x0800 (IPv4).
		The IP header's Protocol field is set to 17 (UDP).
		The UDP destination port number is set to 67.
		This field is optional. If unsupported, broadcast DHCP packets will be blocked when broadcast filtering is enabled. The value shall be set to 0b if unsupported.
3	NetBIOS Packets	1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.
		For the purposes of this filter, NetBIOS broadcast packets are defined to be any packet that meets all of the following requirements:
		• The destination MAC address field is set to the layer 2 broadcast address (FF:FF:FF:FF:FF;FF).
		• The EtherType field is set to 0x0800 (IPv4).
		The IP header's Protocol field is set to 17 (UDP).
		 The UDP destination port number is set to 137 for NetBIOS Name Service or 138 for NetBIOS Datagram Service, per the assignment of IANA well-known ports.
		This field is optional. If unsupported, broadcast NetBIOS packets will be blocked when broadcast filtering is enabled. The value shall be set to $0b$ if unsupported.
431	Reserved	None

2128 8.4.34 Enable Broadcast Filter response (0x90)

- The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Enable Broadcast Filter command and send a response.
- 2131 Currently no command-specific reason code is identified for this response (see Table 71).

2132

Table 71 – Enable Broadcast Filter response packet format

2144 8.4.37 Enable Global Multicast Filter command (0x12)

2145 The Enable Global Multicast Filter command is used to activate global filtering of multicast frames with

2146 optional filtering of specific multicast protocols. Upon receiving and processing this command, the

channel shall only deliver multicast frames that match specific multicast MAC addresses enabled for Pass
 through using this command or the Set MAC Address command.

The Multicast Packet Filter Settings field is used to specify optional, protocol-specific multicast filters that should be activated. The channel indicates which optional multicast filters it supports in the Multicast Filter Capabilities field of the Get Capabilities Response frame defined in 8.4.46. The Management Controller should not set bits in the Multicast Packet Filter Settings field that are not indicated as supported in the Multicast Filter Capabilities field

2153 Multicast Filter Capabilities field.

2154 Neighbor Solicitation messages are sent to a Solicited Node multicast address that is derived from the 2155 target node's IPv6 address. This command may be used to enable forwarding of solicited node

2156 multicasts.

2157 The IPv6 neighbor solicitation filter, as defined in this command, may not be supported by the Network

2158 Controller. In this case, the Management Controller may configure a multicast or mixed MAC address

2159 filter for the specific Solicited Node multicast address using the Set MAC Address command to enable

2160 forwarding of Solicited Node multicasts.

2161 This command shall be implemented if the channel implementation supports accepting all multicast

addresses. An implementation that does not support accepting all multicast addresses shall not
 implement these commands. Pass-through packets with multicast addresses can still be accepted
 depending on multicast address filter support provided by the Set MAC Address command. Multicast filter

2165 entries that are set to be enabled in the Set MAC Address command are accepted; all others are rejected.

Table 74 illustrates the packet format of the Enable Global Multicast Filter command. Unsupported fields

- 2167 should be treated as reserved fields unless otherwise specified.
- 2168

2169

Table 74 – Enable Global Multicast Filter command packet format

2170 Table 75 describes the bit definitions for the Multicast Packet Filter Settings field.

Bit Position	Field Description	Value Description
0	IPv6 Neighbor Advertisement	 1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.
		For the purposes of this specification, an IPv6 Neighbor Advertisement multicast packet is defined to be any packet that meets all of the following requirements:
		• The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This address corresponds to the All_Nodes (FF02::1) multicast address.
		 The EtherType field is set to 0x86DD (IPv6).
		 The IPv6 header's Next Header field is set to 58 (ICMPv6).
		 The ICMPv6 header's Message Type field is set to the following value: 136 – Neighbor Advertisement.
		This field is optional.
1	IPv6 Router Advertisement	 1b = Forward this packet type to the Management Controller. 0b = Filter out this packet type.
		For the purposes of this specification, an IPv6 Router Advertisement multicast packet is defined to be any packet that meets all of the following requirements:
		• The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This corresponds to the All_Nodes multicast address, FF02::1.
		 The EtherType field is set to 0x86DD (IPv6).
		 The IPv6 header's Next Header field is set to 58 (ICMPv6).
		 The ICMPv6 header's Message Type field is set to 134.
		This field is optional.
2	DHCPv6 relay and server multicast	1b = Forward this packet type to the Management Controller.0b = Filter out this packet type.
		For the purposes of this filter, a DHCPv6 multicast packet is defined to be any packet that meets all of the following requirements:
		 The destination MAC address field is set to the layer 2 multicast address 33:33:00:01:00:02 or 33:33:00:01:00:03. These correspond to the IPv6 multicast addresses FF02::1:2 (All_DHCP_Relay_Agents_and_Servers) and FF05::1:3 (All_DHCP_Servers).
		 The EtherType field is set to 0x86DD (IPv6).
		 The IPv6 header's Next Header field is set to 17 (UDP).
		 The UDP destination port number is set to 547.
		This field is optional.

Bit Position	Field Description	Value Description			
3	DHCPv6 multicasts from server to clients	1b = Forward this packet type to the Management Controller.0b = Filter out this packet type.			
	listening on well- known UDP ports	For the purposes of this filter, a DHCPv6 multicast packet is defined to be any packet that meets all of the following requirements:			
		• The destination MAC address field is set to the layer 2 multicast address 33:33:00:01:00:02. These correspond to the IPv6 multicast addresses FF02::1:2 (AII_DHCP_Relay_Agents_and_Servers).			
		 The EtherType field is set to 0x86DD (IPv6). 			
		 The IPv6 header's Next Header field is set to 17 (UDP). 			
		 The UDP destination port number is set to 546. 			
		This field is optional.			
4	IPv6 MLD	1b= Forward this packet type to the Management Controller.0b= Filter out this packet type.			
		For the purposes of this specification, an IPv6 MLD packet is defined to be any packet that meets all of the following requirements:			
		• The destination MAC address field is set to a layer 2 multicast address of the form 33:33:00:00:00:01. This address corresponds to the All_Nodes (FF02::1) multicast address.			
		• The EtherType field is set to 0x86DD (IPv6).			
		 The IPv6 header's Next Header field is set to 58 (ICMPv6). 			
		 The ICMPv6 header's Message Type field is set to one of the following values: 130 (Multicast Listener Query), 131 (Multicast Listener Report), 132 (Multicast Listener Done) 			
		This field is optional.			

Bit Position	Field Description	Value Description
5	IPv6 Neighbor Solicitation	1b = Forward this packet type to the Management Controller.0b = Filter out this packet type.
		For the purposes of this specification, an IPv6 MLD packet is defined to be any packet that meets all of the following requirements:
		• The destination MAC address field is set to a layer 2 multicast address of the form 33:33:FF:XX:XX:This address corresponds to the Solicited Note multicast address where the last three bytes of the destination MAC address are ignored for this filter.
		 The EtherType field is set to 0x86DD (IPv6).
		 The IPv6 header's Next Header field is set to 58 (ICMPv6).
		 The ICMPv6 header's Message Type field is set to one of the following values: 135
		This field is optional.
		IMPLEMENTATION NOTE Enabling of this filter results in receiving all IPv6 neighbor solicitation traffic on this channel. If IPv6 neighbor solicitation traffic for a specific multicast address is of interest, then it is recommended that the MC uses a multicast address filter (configured for the multicast address using the Set MAC Address command) instead of this filter.
316	Reserved	None

2172 **8.4.38 Enable Global Multicast Filter response (0x92)**

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Enable Global Multicast Filter command and send a response.

2175 Currently no command-specific reason code is identified for this response (see Table 76).

2176

Table 76 – Enable Global Multicast Filter response packet format

2023	Checksum					
2445		Pa	ad			

2177 8.4.39 Disable Global Multicast Filter command (0x13)

The Disable Global Multicast Filter command is used to disable global filtering of multicast frames. Upon receiving and processing this command, and regardless of the current state of multicast filtering, the channel shall forward all multicast frames to the Management Controller.

This command shall be implemented on the condition that the channel implementation supports accepting
all multicast addresses. An implementation that does not support accepting all multicast addresses shall
not implement these commands. Pass-through packets with multicast addresses can still be accepted
depending on multicast address filter support provided by the Set MAC Address command. Packets with

- 2185 destination addresses matching multicast filter entries that are set to enabled in the Set MAC Address
- 2186 command are accepted; all others are rejected.
- 2187 Table 77 illustrates the packet format of the Disable Global Multicast Filter command.

2188

2023	Checksum						
2445		Pad					

2194 8.4.41 Set NC-SI Flow Control command (0x14)

The Set NC-SI Flow Control command allows the Management Controller to configure <u>IEEE 802.3</u> pause packet flow control on the NC-SI.

The Set NC-SI Flow Control command is addressed to the package, rather than to a particular channel (that is, the command is sent with a Channel ID where the Package ID subfield matches the ID of the intended package and the Internal Channel ID subfield is set to $0 \times 1F$).

When enabled for flow control, a channel may direct the package to generate and renew 802.3x (XOFF)
PAUSE Frames for a maximum interval of T12 for a single congestion condition. If the congestion
condition remains in place after a second T12 interval expires, the congested channel shall enter the
Initial State and remove its XOFF request to the package. Note that some implementations may have
shared buffering arrangements where all channels within the package become congested simultaneously.
Also note that if channels become congested independently, the package may not immediately go into
the XON state after T12 if other channels within the package are still requesting XOFF.

The setting of <u>IEEE 802.3</u> pause packet flow control on the NC-SI is independent from any arbitration scheme, if any is used.

2209 Table 79 illustrates the packet format of the Set NC-SI Flow Control command.

2210

Table 79 – Set NC-SI Flow Control command packet format

5255	Manufacturer ID (IANA)					
5659		Chec	ksum			

2229 8.4.44.1 NC-SI Version encoding

The NC-SI Version field holds the version number of the NC-SI specification with which the controller is compatible. The version field shall be encoded as follows:

- The 'major', 'minor', and 'update' bytes are BCD-encoded, and each byte holds two BCD digits.
- The 'alpha' byte holds an optional alphanumeric character extension that is encoded using the ISO/IEC 8859-1 Character Set.
- The semantics of these fields follow the semantics specified in <u>DSP4014</u>.
- The value 0x00 in the Alpha1 or Alpha2 fields means that the corresponding alpha field is not used. The Alpha1 field shall be used first.
- The value $0 \ge F$ in the most-significant nibble of a BCD-encoded value indicates that the mostsignificant nibble should be ignored and the overall field treated as a single digit value.
- A value of 0xFF in the update field indicates that the entire field is not present. 0xFF is not allowed as a value for the major or minor fields.

2242	EXAMPLE:	Version 3.7.10a	\rightarrow	0xF3F7104100				
2243		Version 10.01.7	\rightarrow	0x1001F70000				
2244		Version 3.1	\rightarrow	0xF3F1FF0000				
2245		Version 1.0a	\rightarrow	0xF1F0FF4100				
2246		Version 1.0ab	\rightarrow	0xF1F0FF4142	(Alphal =	0x41,	Alpha2	$= 0 \times 42$)

2247 8.4.44.2 Firmware Name encoding

The Firmware Name String shall be encoded using the ISO/IEC 8859-1 Character Set. Strings are leftjustified where the leftmost character of the string occupies the most-significant byte position of the Firmware Name String field, and characters are populated starting from that byte position. The string is null terminated if the string is smaller than the field size. That is, the delimiter value, 0×00 , follows the last character of the string occupies fewer bytes than the size of the field allows. A delimiter is not required if the string occupies the full size of the field. Bytes following the delimiter (if any) should be ignored and can be any value.

2255 8.4.44.3 Firmware Version encoding

To facilitate a common way of representing and displaying firmware version numbers across different
vendors, each byte is hexadecimal encoded where each byte in the field holds two hexadecimal digits.
The Firmware Version field shall be encoded as follows. The bytes are collected into a single 32-bit field
where each byte represents a different 'point number' of the overall version. The selection of values that
represent a particular version of firmware is specific to the Network Controller vendor.

2261 Software displaying these numbers should not suppress leading zeros, which should help avoid user 2262 confusion in interpreting the numbers. For example, consider the two values 0×05 and 0×31 . 2263 Numerically, the byte 0×31 is greater that 0×05 , but if leading zeros were incorrectly suppressed, the two 2264 displayed values would be ".5" and ".31", respectively, and a user would generally interpret 0.5 as 2265 representing a greater value than 0.31 instead of 0.05 being smaller than 0.31. Similarly, if leading zeros 2266 were incorrectly suppressed, the value 0×01 and 0×10 would be displayed as 0.1 and 0.10, which could 2267 potentially be misinterpreted as representing the same version instead of 0.01 and 0.10 versions.

2268EXAMPLE: $0 \times 00030217 \rightarrow$ Version 00.03.02.172269 $0 \times 010100A0 \rightarrow$ Version 01.01.00.A0

2270 8.4.44.4 PCI ID fields

These fields (PCI DID, PCI VID, PCI SSID, PCI SVID) hold the PCI ID information for the Network
Controller when the Network Controller incorporates a PCI or PCI Express[™] interface that provides a
host network interface connection that is shared with the NC-SI connection to the network.

If this field is not used, the values shall all be set to zeros (0000h). Otherwise, the fields shall hold the
PCI ID information for the host interface as defined by the version of the PCI/PCI Express[™] specification
to which the device's interface was designed.

2277 8.4.44.5 Manufacturer ID (IANA) field

The Manufacturer ID holds the <u>IANA Enterprise Number</u> for the manufacturer of the Network Controller as a 32-bit binary number. If the field is unused, the value shall be set to 0xFFFFFFFF.

2280 8.4.45 Get Capabilities command (0x16)

п

The Get Capabilities command is used to discover additional optional functions supported by the channel, such as the number of unicast/multicast addresses supported, the amount of buffering in bytes available for packets bound for the Management Controller, and so on.

Table 85 illustrates the packet format for the Get Capabilities command.

2285

Table 85 – Get Capabilities command packet format

	Bits			
Bytes	3124	2316	1508	0700
0015	NC-SI Control Message Header			
1619	Checksum			
2045	Pad			

2286 8.4.46 Get Capabilities response (0x96)

In the absence of any errors, the channel shall process and respond to the Get Capabilities Command
and send the response packet shown in Table 86. Currently no command-specific reason code is
identified for this response.

2290

Table 86 – Get Capabilities response packet format

_	Bits			
Bytes	3124	2316	1508	0700
0015	NC-SI Control Message Header

4043	VLAN Filter Count	Mixed Filter Count	Multicast Filter Count	Unicast Filter Count
4447	Reserved		VLAN Mode Support	Channel Count
4851	Checksum			

2291 **8.4.46.1 Capabilities Flags field**

The Capabilities Flags field indicates which optional features of this specification the channel supports, as described in Table 87.

Table 87 – Capabilities Flags bit definitions

Bit Position	Field Description	Value Description		
0	Hardware Arbitration Capability	 0b = Hardware arbitration capability is not supported by the package. 1b = Hardware arbitration capability is supported by the package. 		
1	Host NC Driver Status	 0b = Host NC Driver Indication status is not supported. 1b = Host NC Driver Indication status is supported. See Table 49 for the definition of Host NC Driver Indication Status. 		
2	Network Controller to Management Controller Flow Control Support	 0b = Network Controller to Management Controller flow control is not supported. 1b = Network Controller to Management Controller flow control is supported. 		
3	Management Controller to Network Controller Flow Control Support	 0b = Management Controller to Network Controller flow control is not supported. 1b = Management Controller to Network Controller flow control is supported. 		
4	All multicast addresses support	 0b = The channel cannot accept all multicast addresses. The channel does not support enable/disable global multicast commands. 1b = The channel can accept all multicast addresses. The channel supports enable/disable global multicast commands. 		
65	Hardware Arbitration Implementation Status	 00b = Unknown 01b = Hardware arbitration capability is not implemented for the package on the given system. 10b = Hardware arbitration capability is implemented for the package on the given system. 11b = Reserved. 		
731	Reserved	Reserved		

2295 8.4.46.2 Broadcast Packet Filter Capabilities field

2296 The Broadcast Packet Filter Capabilities field defines the optional broadcast packet filtering capabilities that the channel supports. The bit definitions for this field correspond directly with the bit definitions for the 2297 Broadcast Packet Filter Settings field defined for the Enable Broadcast Filter command in Table 70. A bit 2298 2299 set to 1 indicates that the channel supports the filter associated with that bit position; otherwise, the 2300 channel does not support that filter.

2301 8.4.46.3 Multicast Packet Filter Capabilities field

2302 The Multicast Packet Filter Capabilities field defines the optional multicast packet filtering capabilities that 2303 the channel supports. The bit definitions for this field correspond directly with the bit definitions for the 2304 Multicast Packet Filter Settings field defined for the Enable Global Multicast Filter command in Table 75. 2305 A bit set to 1 indicates that the channel supports the filter associated with that bit position; otherwise, the

2306 channel does not support that filter.

2307 8.4.46.4 Buffering Capability field

The Buffering Capability field defines the amount of buffering in bytes that the channel provides for inbound packets destined for the Management Controller. The Management Controller may make use of this value in software-based Device Selection implementations to determine the relative time for which a specific channel may be disabled before it is likely to start dropping packets. A value of 0 indicates that the amount of buffering is unspecified.

2313 8.4.46.5 AEN Control Support field

The AEN Control Support field indicates various standard AENs supported by the implementation. The format of the field is shown in Table 39.

2316 8.4.46.6 VLAN Filter Count field

The VLAN Filter Count field indicates the number of VLAN filters, up to 15, that the channel supports, as defined by the Set VLAN Filter command.

2319 8.4.46.7 Mixed, Multicast, and Unicast Filter Count fields

- The Mixed Filter Count field indicates the number of mixed address filters that the channel supports. A mixed address filter can be used to filter on specific unicast or multicast MAC addresses.
- The Multicast Filter Count field indicates the number of multicast MAC address filters that the channel supports.
- The Unicast Filter Count field indicates the number of unicast MAC address filters that the channel supports.
- The channel is required to support at least one unicast or mixed filter, such that at least one unicast MAC address can be configured on the interface. The total number of unicast, multicast, and mixed filters shall not exceed 8.

2329 8.4.46.8 VLAN Mode Support field

- The VLAN Mode Support field indicates various modes supported by the implementation. The format of field is defined in Table 88.
- 2332

Table 88 – VLAN Mode Support bit definitions

Bit Position	Field Description	Value Description
0	VLAN only	1 = VLAN shall be supported in the implementation.
1	VLAN + non-VLAN	0 = Filtering 'VLAN + non-VLAN' traffic is not supported in the implementation.
		1 = Filtering 'VLAN + non-VLAN' traffic is supported in the implementation.
2	Any VLAN + non-VLAN	0 = Filtering 'Any VLAN + non-VLAN' traffic is not supported in the implementation.
		1 = Filtering 'Any VLAN + non-VLAN' traffic is supported in the implementation.
37	Reserved	0

2333 8.4.46.9 Channel Count field

2334 The Channel Count field indicates the number of channels supported by the Network Controller.

2335 8.4.47 Get Parameters command (0x17)

The Get Parameters command can be used by the Management Controller to request that the channel send the Management Controller a copy of all of the currently stored parameter settings that have been put into effect by the Management Controller, plus "other" Host/Channel parameter values that may be added to the Get Parameters Response Payload.

Table 89 illustrates the packet format for the Get Parameters command.

2341

Table 89 – Get Parameters command packet format

	Bits			
Bytes	3124	2316	1508	0700
0015	NC-SI Control Message Header			
1619	Checksum			
2045	Pad			

2342 **8.4.48 Get Parameters response (0x97)**

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get Parameters command and send a response. As shown in Table 90, each parameter shall return the value that was set by the Management Controller. If the parameter is not supported, 0 is returned. Currently no command-specific reason code is identified for this response.

The payload length of this response packet will vary according to how many MAC address filters or VLAN filters the channel supports. All supported MAC addresses are returned at the end of the packet, without any intervening padding between MAC addresses.

2350 MAC addresses are returned in the following order: unicast filtered addresses first, followed by multicast 2351 filtered addresses, followed by mixed filtered addresses, with the number of each corresponding to those reported through the Get Capabilities command. For example, if the interface reports four unicast filters, 2352 2353 two multicast filters, and two mixed filters, then MAC addresses 1 through 4 are those currently 2354 configured through the interface's unicast filters, MAC addresses 5 and 6 are those configured through 2355 the multicast filters, and 7 and 8 are those configured through the mixed filters. Similarly, if the interface 2356 reports two unicast filters, no multicast filters, and six mixed filters, then MAC addresses 1 and 2 are 2357 those currently configured through the unicast filters, and 3 through 8 are those configured through the 2358 mixed filters.

431	Reserved	Reserved

2368 8.4.49 Get Controller Packet Statistics command (0x18)

The Get Controller Packet Statistics command may be used by the Management Controller to request a copy of the aggregated packet statistics that the channel maintains for its external interface to the LAN network. The statistics are an aggregation of statistics for both the host side traffic and the NC-SI Passthrough traffic.

2373

Table 95 – Get Controller Packet Statistics command packet format

Table 97 – Get Controller Packet Statistics counters

Counter Number	Name	Meaning
0	Total Bytes Received	Counts the number of bytes received
1	Total Bytes Transmitted	Counts the number of bytes transmitted
2	Total Unicast Packets Received	Counts the number of good (FCS valid) packets received that passed L2 filtering by a specific MAC address
3	Total Multicast Packets Received	Counts the number of good (FCS valid) multicast packets received
4	Total Broadcast Packets Received	Counts the number of good (FCS valid) broadcast packets received
5	Total Unicast Packets Transmitted	Counts the number of good (FCS valid) packets transmitted that passed L2 filtering by a specific MAC address
6	Total Multicast Packets Transmitted	Counts the number of good (FCS valid) multicast packets transmitted
7	Total Broadcast Packets Transmitted	Counts the number of good (FCS valid) broadcast packets transmitted
8	FCS Receive Errors	Counts the number of receive packets with FCS errors

Network Controller Sideband Interface (NC-SI) Specification

Counter Number	Name	Meaning
9	Alignment Errors	Counts the number of receive packets with alignment errors
10	False Carrier Detections	Counts the false carrier errors reported by the PHY
11	Runt Packets Received	Counts the number of received frames that passed address filtering, were less than minimum size (64 bytes from <destination address=""> through <fcs>, inclusively), and had a valid FCS</fcs></destination>
12	Jabber Packets Received	Counts the number of received frames that passed address filtering, were greater than the maximum size, and had a valid FCS
13	Pause XON Frames Received	Counts the number of XON packets received from the network
14	Pause XOFF Frames Received	Counts the number of XOFF packets received from the network
15	Pause XOFF Frames Transmitted	Counts the number of XON packets transmitted to the network
16	Pause XOFF Frames Transmitted	Counts the number of XOFF packets transmitted to the network
17	Single Collision Transmit Frames	Counts the number of times that a successfully transmitted packet encountered a single collision
18	Multiple Collision Transmit Frames	Counts the number of times that a transmitted packet encountered more than one collision but fewer than 16
19	Late Collision Frames	Counts the number of collisions that occurred after one slot time (defined by <u>IEEE 802.3</u>)
20	Excessive Collision Frames	Counts the number of times that 16 or more collisions occurred on a single transmit packet
21	Control Frames Received	Counts the number of MAC control frames received that are <i>not</i> XON or XOFF flow control frames
22	64 Byte Frames Received	Counts the number of good packets received that are exactly 64 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
23	65–127 Byte Frames Received	Counts the number of good packets received that are 65–127 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
24	128–255 Byte Frames Received	Counts the number of good packets received that are 128–255 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
25	256–511 Byte Frames Received	Counts the number of good packets received that are 256–511 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
26	512–1023 Byte Frames Received	Counts the number of good packets received that are 512–1023 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>

Network Controller Sideband Interface (NC-SI) Specification

Counter Number	Name	Meaning
27	1024–1522 Byte Frames Received	Counts the number of good packets received that are 1024–1522 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
28	1523–9022 Byte Frames Received	Counts the number of received frames that passed address filtering and were greater than 1523 bytes in length
29	64 Byte Frames Transmitted	Counts the number of good packets transmitted that are exactly 64 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
30	65–127 Byte Frames Transmitted	Counts the number of good packets transmitted that are 65–127 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
31	128–255 Byte Frames Transmitted	Counts the number of good packets transmitted that are 128–255 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
32	256–511 Byte Frames Transmitted	Counts the number of good packets transmitted that are 256–511 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
33	512–1023 Byte Frames Transmitted	Counts the number of good packets transmitted that are 512–1023 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
34	1024–1522 Byte Frames Transmitted	Counts the number of good packets transmitted that are 1024–1522 bytes (from <destination address=""> through <fcs>, inclusively) in length</fcs></destination>
35	1523–9022 Byte Frames Transmitted	Counts the number of transmitted frames that passed address filtering and were greater than 1523 in length
36	Valid Bytes Received	Counts the bytes received in all packets that did not manifest any type of error
37	Error Runt Packets Received	Counts the number of invalid frames that were less than the minimum size (64 bytes from <destination Address> through <fcs>, inclusively)</fcs></destination
38	Error Jabber Packets Received	Counts Jabber packets, which are defined as packets that exceed the programmed MTU size and have a bad FCS value

The Network Controller shall also indicate in the Counters Cleared from Last Read fields whether the corresponding field has been cleared by means other than NC-SI (possibly by the host) since it was last read by means of the NC-SI. Counting shall resume from 0 after a counter has been cleared. The

2386 Counters Cleared from Last Read fields format is shown in Table 98.

2387 Currently no command-specific reason code is identified for this response.

Table 98 – Counters Cleared from Last Read Fields format

Field	Bits	Mapped to Counter Numbers
MS Bits	06	3238
	731	Reserved
LS Bits	031	031

IMPLEMENTATION NOTE The Get Controller Packet Statistics response contains the following counters related
 to flow control: Pause XON Frames Received, Pause XOFF Frames Received, Pause XON Frames Transmitted, and
 Pause XOFF Frames Transmitted. An implementation may or may not include Priority-Based Flow Control (PFC)
 packets in these counters.

2393 8.4.51 Get NC-SI Statistics command (0x19)

In addition to the packet statistics accumulated on the LAN network interface, the channel separately
 accumulates a variety of NC-SI specific packet statistics for the channel. The Get NC-SI Statistics
 command may be used by the Management Controller to request that the channel send a copy of all
 current NC-SI packet statistic values for the channel. The implementation may or may not include
 statistics for commands that are directed to the package.

- 2399 Table 99 illustrates the packet format of the Get NC-SI Statistics command.
- 2400

4043	NC-SI Transmit Packets				
4447	AENs Sent				
4851		Chec	ksum		

The Get NC-SI Statistics Response frame contains a set of statistics counters that monitor the NC-SI traffic in the Network Controller. Counters that are supported shall be reset to 0x0 when entering into the Initial State and after being read. Implementation of the counters shown in Table 101 is optional. The Network Controller shall return any unsupported counter with a value of 0xFFFFFFFF. Counters may wraparound or stop if they reach 0xFFFFFFFE. It is vendor specific how NC-SI commands that are sent to the package ID are included in the NC-SI statistics.

2411 Currently no command-specific reason code is identified for this response.

2412

Table 101 – Get NC-SI Statistics counters

Counter Number	Name	Meaning
1	NC-SI Commands Received	For packets that are not dropped, this field returns the number of NC-SI Control Messages received and identified as NC-SI commands.
2	NC-SI Control Messages Dropped	Counts the number of NC-SI Control Messages that were received and dropped (Packets with correct FCS and EtherType, but are dropped for one of the other reasons listed in 6.9.1.1). NC-SI Control Messages that were dropped because the channel ID was not valid may not be included in this statistics counter.
3	NC-SI Unsupported Commands Received	Counts the number of NC-SI command packets that were received, but are not supported. (Network controller responded to the command with a Command Unsupported response code).
4	NC-SI Command Checksum Errors	Counts the number of NC-SI Control Messages that were received but dropped because of an invalid checksum (if checksum is provided and checksum validation is supported by the channel)

Counter Number	Name	Meaning
5	NC-SI Receive Packets	Counts the total number of NC-SI Control Messages received. This count is the sum of NC- SI Commands Received and NC-SI Control Messages Dropped.
6	NC-SI Transmit Packets	Counts the total number of NC-SI Control Messages transmitted to the Management Controller. This count is the sum of NC-SI responses sent and AENs sent.
7	AENs Sent	Counts the total number of AEN packets transmitted to the Management Controller

2413 8.4.53 Get NC-SI Pass-through Statistics command (0x1A)

- 2414 The Get NC-SI Pass-through Statistics command may be used by the Management Controller to request
- that the channel send a copy of all current NC-SI Pass-through packet statistic values.
- Table 102 illustrates the packet format of the Get NC-SI Pass-through Statistics command.

6467	Checksum				

2428

Table 104 – Get NC-SI Pass-through Statistics counters

Counter Number	Name	Meaning
1	Total Pass-through TX Packets Received (Management Controller to Channel)	Counts the number of Pass-through packets forwarded by the channel to the LAN
2	Total Pass-through TX Packets Dropped (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were dropped by the Network Controller
3	Pass-through TX Packet Channel State Errors (Management Controller to Channel)	Counts the number of egress management packets (Management Controller to Network Controller) that were dropped because the channel was in the disabled state when the packet was received
4	Pass-through TX Packet Undersized Errors (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were undersized (under 64 bytes, including FCS)
5	Pass-through TX Packet Oversized Errors (Management Controller to Channel)	Counts the number of Pass-through packets from the Management Controller that were oversized (over 1522 bytes, including FCS)
6	Total Pass-through RX Packets Received On the LAN Interface (LAN to Channel)	Counts the number of Pass-through packets that were received on the LAN interface of the channel. This counter does not necessarily count the number of packets that were transmitted to the Management Controller, because some of the packets might have been dropped due to RX queue overflow.
7	Total Pass-through RX Packets Dropped (LAN to Channel)	Counts the number of Pass-through packets that were received on the LAN interface of the channel but were dropped and not transmitted to the Management Controller
8	Pass-through RX Packet Channel State Errors (LAN to Channel)	Counts the number of ingress management packets (channel to Management Controller) that were dropped because the channel was in the disabled state when the packet was received. The NC may also count packets that were dropped because the package was in the deselected state.

Network Controller Sideband Interface (NC-SI) Specification

Counter Number	Name	Meaning
9	Pass-through RX Packet Undersized Errors (LAN to Channel)	Counts the number of Pass-through packets from the LAN that were undersized (under 64 bytes, including FCS)
10	Pass-through RX Packet Oversized Errors (LAN to Channel)	Counts the number of Pass-through packets from the LAN that were oversized (over 1522 bytes, including FCS)

2429 Currently no command-specific reason code is identified for this response.

2430 8.4.55 Get Package Status command (0x1B)

2431The Get Package Status command provides a way for a Management Controller to explicitly query the2432status of a package. The Get Package Status command is addressed to the package, rather than to a2433particular channel (that is, the command is sent with a Channel ID where the Package ID subfield

2434 matches the ID of the intended package and the Internal Channel ID subfield is set to 0x1F).

2435 Table 105 illustrates the packet format of the Get Package Status command.

2441 8.4.57 Get PF Assignment command (0x1C)

2442 The Get PF Assignment command is a Package command that allows the Management controller to

2443 receive the list of PCI Physical Functions (partitions) currently assigned to channels (network ports) in the

- 2444 package, their enablement state and conditionally what PCI bus they are assigned to if multi-host or multi-
- 2445 homing is supported by the controller.
- 2446 See the Set PF Assignment command description for additional information.
- 2447 <u>Table 108 illustrates the packet format of the Get PF Assignment Command.</u>
- 2448

Table 108 – Get PF Assignment Command Packet Format

2455

2456 8.4.58.1 Channel Function Assignment bitmap Field

The Channel Function Assignment bitmap is a 32-bit field in which each bit position corresponds to a
 physical function in the device. If the physical function is assigned to the channel (port), even if it not
 currently enabled, the bit value shall be set to 0b1.

2460

Table 110 – Channel Function Assignment bitmap Field

<u>Bit</u> Position	Field Description	Value Description
<u>0</u>	F0 status	$\underline{0b} = F0$ is not assigned on the channel (port). $\underline{1b} = F0$ is assigned on the channel (port).
<u>1</u>	<u>F1 status</u>	$\frac{0b}{1b} = F1 \text{ is not assigned on the channel (port).}$ $\frac{1b}{1b} = F1 \text{ is assigned on the channel (port).}$
<u></u>		<u></u>
<u>15</u>	F15 status	$\frac{0b}{1b} = F15 \text{ is not assigned on the channel (port).}$ $\frac{1b}{1b} = F15 \text{ is assigned on the channel (port)}$

2461

2462 8.4.58.2 Function Enablement bitmap Field

2463The Function Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical2464function in the device.

Table 111 – Function Enablement bitmap Field

<u>Bit</u> Position	Field Description	Value Description
<u>0</u>	F0 status	0b = F0 is not enabled on the specified channel (port). 1b = F0 is enabled on the specified channel (port).
<u>1</u>	<u>F1 status</u>	0b = F1 is not enabled on the specified channel (port). 1b = F1 is enabled on the specified channel (port).
<u></u>	<u></u>	
<u>15</u>	F15 status	$\frac{0b}{1b} = F15 \text{ is not enabled on the specified channel (port).}$ $\frac{1b}{1b} = F15 \text{ is enabled on the specified channel (port)}$

2466

2467 8.4.58.3 PCI Bus Assignment bitmap Field

The PCI Bus Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical
 function in the device.

2470

Table 112 – PCI Bus Assignment bitmap Field

Bit Position	Field Description	Value Description
<u>0</u>	F0 status	<u>Ob = F0 is not assigned on the specified PCI Bus.</u> <u>Ib = F0 is assigned on the specified PCI Bus.</u>
1	<u>F1 status</u>	<u>Ob = F1 is not assigned on the specified PCI Bus.</u> <u>Ib = F1 is assigned on the specified PCI Bus.</u>
<u></u>	<u></u>	<u></u>
<u>15</u>	<u>F15 status</u>	<u>Ob = F15 is not assigned on the specified PCI Bus.</u> <u>1b = F15 is assigned on the specified PCI Bus</u>

8.4.59 Set PF Assignment command (0x1D) 2472

The Set PF Assignment command is a Package command that allows the Management controller to 2473 2474 enable, disable and assign PCI Physical Functions (partitions) in the controller to the channels (network 2475 ports), and, if applicable, to different PCI buses in multi-home or multi-host configurations. 2476 The format of the command payload is dependent on the numbers of Physical Functions, Channels and PCI Buses supported by the controller: 2477 1. The number of Function Assignments bitmap fields shall be determined by the value (c) of the 2478 Channel Count field in the Get Capabilities response. 2479 2480 2. The number of Physical Functions allowed to be configured in the Function Assignment and Enablement bitmap fields shall be determined by the value of the <Physical Function Count> field 2481 2482 in the <Additional Capabilities> response. Assignment in all bitmaps starts at bit 0 and continues sequentially for the number of Functions supported. To support various implementation 2483 2484 architectures, the definition of assignment/enablement rules is beyond the scope of this 2485 specification. 2486 3. If the value (b) of the <PCI Bus Count> field in the <Additional Capabilities> response is greater 2487 than 1, the Controller shall also include that number of PCI Bus Function Assignment bitmap 2488 fields in the command. Controllers that do not support multiple PCI interfaces shall not implement PCI Bus Host Function Assignment bitmap fields. PCI Bus 0 shall be used if the Controller is 2489 2490 configured for single bus operation.

- 2491 Table 113 illustrates the packet format of the Set PF Assignment Command.

2493 8.4.59.1 Channel Function Assignment bitmap Field

2494 The Channel Function Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical function in the device. If the physical function is assigned to the channel (port), even if it not 2495 2496

currently enabled, the bit value shall be set to 0b1.

Table 114 – Channel Function Assignment bitmap Field

<u>Bit</u> Position	Field Description	Value Description
<u>0</u>	F0 status	0b = F0 is not assigned on the channel (port). 1b = F0 is assigned on the channel (port).
<u>1</u>	<u>F1 status</u>	0b = F1 is not assigned on the channel (port). 1b = F1 is assigned on the channel (port).
<u></u>	<u></u>	<u></u>
<u>15</u>	F15 status	$\frac{0b}{1b} = F15 \text{ is not assigned on the channel (port).}$ $\frac{1b}{1b} = F15 \text{ is assigned on the channel (port)}$

2498 8.4.59.2 Function Enablement bitmap Field

2499 The Function Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical
 2500 function in the device.

2501

Table 115 – Function Enablement bitmap Field

Bit Position	Field Description	Value Description
<u>0</u>	<u>F0 status</u>	0b = F0 is not enabled on the specified channel (port). 1b = F0 is enabled on the specified channel (port).
1	<u>F1 status</u>	0b = F1 is not enabled on the specified channel (port). 1b = F1 is enabled on the specified channel (port).
<u></u>	<u></u>	
<u>15</u>	<u>F15 status</u>	$\frac{0b}{1b} = F15 \text{ is not enabled on the specified channel (port).}$ $\frac{1b}{1b} = F15 \text{ is enabled on the specified channel (port)}$

2502

2503 8.4.59.3 PCI Bus Assignment bitmap Field

The PCI Bus Assignment bitmap is a 32-bit field in which each bit position corresponds to a physical
 function in the device.

2506

Table 116 – PCI Bus Assignment bitmap Field

Bit Position	Field Description	Value Description
<u>0</u>	<u>F0 status</u>	$\frac{0b = F0 \text{ is not assigned on the specified PCI Bus.}}{1b = F0 \text{ is assigned on the specified PCI Bus.}}$

2525

2526 8.4.62 Get Boot Config Response (0x9E)

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get Boot
 Config command and send a response.

2529 The Get Boot Config Response frame contains the currently stored settings for the specified Boot

2530 Protocol type contained in the controller's NVRAM that the channel/PF/partition will use in a boot

2531 operation done locally by the adapter. Settings that the Controller supports but does not have a value for

2532 (e.g., have no initial or current value) should be included in the Response and have a length of 0.

Network Controller Sideband Interface (NC-SI) Specification

2533 <u>All attribute values returned by this command shall be in unterminated ASCII string format.</u>

2534 Table 120 illustrates the packet format of the Get Boot Config Response.

2543 8.4.63 Set Boot Config Command (0x1F)

- The Set Boot Config Command allows the Management Controller to send to the channel/PF/ partition
 the Boot settings to be used by the channel/PF/partition in conducting boot operations of the specified
 type.
- 2547 <u>The Network Controller shall apply the attribute values in the order received in this command (e.g., TLV1</u> 2548 <u>before TLV2, etc.) so that any dependency relationships are maintained.</u>
- 2549 All attribute values specified in this command shall be in unterminated ASCII string format.
- 2550 <u>A TLV length value of 0 indicates the clearing of the current value of the attribute to null or no value.</u>
- 2551 <u>A maximum of 32 TLVs may be sent in any one instance of the Set Boot Config command.</u>
- 2552 If the command is sent to a destination that exists but that does not support the specified Boot Protocol
- 2553 type, the command execution shall fail with a response indicating an unsupported command.
- 2554

2555 8.4.64 Set Boot Config Response (0x9F)

- In the absence of any errors, the channel shall process and respond to the Set Boot Config Command
 and send the response packet shown in Table 126.
- 2558The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Set Boot2559Config command and send a response.
- 2560 If the command is sent to a destination that exists but that does not support the specified Boot Protocol
 2561 type, the command response shall indicate an unsupported command.
- 2562 If there are errors in any of the TLVs included in the Set command, the entire command is deemed to fail
 2563 and no configuration changes are to be made by the controller. The TLV Error Reporting field shall be
 2564 used to provide individual status reporting on the TLVs received.

2566

2567 8.4.64.1 <u>TLV Error Reporting Field</u>

2568The TLV Error Reporting field is a bit-map indicating which TLVs were processed successfully and which2569were not in the incoming Set command. The bit order corresponds to the order of TLVs in the incoming2570Set command. There is a 1:1 correspondence between incoming TLVs and the active bits in this field. If2571less than 32 TLVs are transmitted, the bits corresponding to the unsent TLVs shall be set to 0.

2572

Table 127 – TLV Error Reporting Field

Bit Position	Field Description	Value Description	
<u>0</u>	TLV0 status	0b = 0 No error detected in TLV0	
		<u>Ob = 1 Error detected in TLV0</u>	
<u>1</u>	TLV1 status	1b = 0 No error detected in TLV1 or TLV1 not present	
		<u>$1b = 1$ Error detected in TLV1</u>	
		0x??-0xFF = Reserved	

2574 8.4.65 Get iSCSI Offload Statistics Command (0x20)

- 2575 The Get iSCSI Offload Statistics Command allows the Management Controller to query the
- 2576 <u>channel/PF/partition for iSCSI Offload Statistics.</u>
- 2577 Implementation of this command is conditional and is required only for Ethernet Controllers that support
 2578 the iSCSI Offload feature and do not include iSCSI Offload statistics in general LAN statistics reporting.
- 2579 Table 128 illustrates the packet format of the Get iSCSI Offload Statistics Command.
- 2580

2618

Table 134 – Get FC Statistics

Name	Meaning
Total FC Frames Received	Counts the number of FC frames received by the port
Total FC Frames Transmitted	Counts the number of FC frames transmitted by the port
Receive KB Count	Counts the number of kilobytes transmitted by the port
Transmit KB Count	Counts the number of kilobytes transmitted by the port
FC Sequences Received	Counts the number of FC sequences received by the port
FC Sequences Transmitted	Counts the number of FC sequences transmitted by the port
Link Failures	Counts the number of times the link has failed.
Loss of Signal	Counts the number of times the signal was lost.
Invalid CRCs	Counts the number of CRC errors detected.

2619

2620 8.4.69 Get FC Link Status Command (0x??)

The Get FC Link Status command allows the Management Controller to query the channel for potential link status and error conditions (see Table 135).

Implementation of this command is conditional and is required only for controllers supporting native FibreChannel.

2626

Table 135 – Get FC Link Status Command Packet Format

2690

Table 146 – InfiniBand Link Status Definitions

Name	Direction	Description	
IB Link Active Width	ТХ	When Link Type is InfiniBand and physical link is up, this field reflects the active link width. Otherwise this field returns 0b.	
		Bit $0 - 1b = 1X$	
		Bit 1 - 1b = 2X	
		Bit 2 - 1b = 4X	
		Bit 3 - 1b = 8X Bits 7:4 Reserved	
IB Link Supported Width	RX	When Link Type is InfiniBand, this field reflects the supported link widths. When Link Type is Ethernet, this field returns 0.	
		Bit 0 - 1b = 1X	
		Bit 1 - 1b = 2X	
		Bit 2 - 1b = 4X	
		Bit 3 - 1b = 8X	
		Bits 7:4 Reserved	
Link Type	ТХ	Reflects the configured link type.	
		Bit 0 - 0b = Ethernet 1b = InfiniBand	
Phys State	RX	The physical link state as specified in IB spec (PortInfoPortPhysicalState)	
		0x0 = Used when Link Type is Ethernet	
		0x1 = Sleep	
		0x2 = Polling	
		0x3 = Disabled	
		0x4 = PortConfigurationTraining	
		0x5 = LinkUp	
		0x6 = LinkErrorRecovery 0x7 = PhyTest	

Name	Direction	Description	
Log State	ТХ	The logical port state of the physical port as specified in IB spec (PortInfo.PortState)	
		0x0: Used when Link Type is Ethernet	
		0x1: Down	
		0x2: Init	
		0x3: Arm	
		0x4: Active	
IB Link Active Speed	тх	When Link Type is InfiniBand and the physical link is up, this field reflects the active link speed. Otherwise this field returns 0x00.	
		Bit $0 - 1b = SDR$	
		Bit 1 - 1b = DDR	
		Bit 2 - 1b = QDR	
		Bit 3 - 1b = FDR10	
		Bit 4 - 1b = FDR	
		Bit 5 - 1b = EDR	
		Bit 6 - 1b = HDR	
		Bit 7 - 1b = NDR	
IB Link Supported Speed	RX	When Link Type is InfiniBand, this field reflects the supported link speeds. When Link Type is Ethernet this field returns 0x00.	
		Bit 0 - 1b = SDR	
		Bit 1 - 1b = DDR	
		Bit 2 - 1b = QDR	
		Bit 3 - 1b = FDR10	
		Bit 4 - 1b = FDR	
		Bit 5 - 1b = EDR	
		Bit 6 - 1b = HDR	
		Bit 7 - 1b = NDR	

2694 8.4.77 Get IB Statistics Command (0x66)

The Get IB Statistics Command allows the Management Controller to query the channel for the IB
 Statistics. Implementation of this command is conditional and is required only for controllers supporting
 native InfiniBand.

2698 Table 147 illustrates the packet format of the Get IB Statistics Command.

Table 149 – IB Statistics Counter Definitions

Name	Direction	Description
PortXmitData	ТХ	Total number of data octets, divided by 4 (lanes), transmitted on all VLs.
PortRcvData	RX	Total number of data octets, divided by 4 (lanes), received on all VLs.
PortXmitPkts	ТХ	Total number of packets transmitted on all VLs from this port. This may include packets with errors.
PortRcvPkts	RX	Total number of packets (this may include packets containing Errors.
PortXmitWait	ТХ	The number of ticks during which the port had data to transmit but no data was sent during the entire tick (either because of insufficient credits or because of lack of arbitration).
PortXmitDiscard	ТХ	Total number of outbound packets discarded by the port because the port is down or congested.
SymbolErrorCounter	RX	Total number of minor link errors detected on one or more physical lanes.
LinkErrorRecoveryCounter	RX	Total number of times the Port Training state machine has successfully completed the link error recovery process.
LinkDownedCounter	RX	Total number of times the Port Training state machine has failed the link error recovery process and downed the link.
PortRcvErrors	RX	Total number of packets containing an error that were received on the port.
PortRcvRemotePhysicalErrors	RX	Total number of packets marked with the EBP delimiter received on the port.
PortRcvSwitchRelayErrors	RX	Total number of packets received on the port that were discarded because they could not be forwarded by the switch relay.
LocalLinkIntegrityErrors	RX	The number of times that the count of local physical errors exceeded the threshold specified by LocalPhyErrors.
ExcessiveBufferOverrun	RX	The number of times that OverrunErrors consecutive flow control update periods occurred, each having at least one overrun error.
VL15Dropped	RX	Number of incoming VL15 packets dropped due to resource limitations (e.g., lack of buffers) of the port.

2711

2712 8.4.79 Set Operating Mode Command (0x67)

Need a command that switches the device/channel (port) between operating modes, in this case Ethernetand InfiniBand. May not be the only example

2715 8.4.80 Set Operating Mode Response (0xE7)

2716 Response format for the above

2717 8.4.81 Get ASIC Temperature (0x23)

The Get ASIC Temperature command allows the Management controller to query for temperature values from the Controller's on-chip thermal sensor(s) or alternately from attached devices.

The Get ASIC Temperature Command is defined as both a package level command and a channel command. This means the command can be addressed either to the package (that is, the command is sent with a Channel ID set to $0 \times 1F$), or addressed to a specific channel in the package.

When sent as a package command, the internal temperature of the controller is returned. If the controller has multiple internal temperature sensors, the highest measured temperature with respect to its threshold shall be returned.

In cases where there are other devices connected to the controller that can also report silicon
temperature via the controller (such as one or more external PHYs), then the channel version of the
command is used and the response contains the temperature data and threshold from the external device
on that channel. Multiple sensor implementations in the external device shall be handled as described
above.

2731 Table 150 illustrates the packet format of the Get ASIC Temperature Command.

2732

Table 150 – Get ASIC Temperature Command Packet

	Bits					
Bytes	3124 2316 1508 0700

2023	Checksum (32) Checksum (10)					
2445	Pad					

2733

2734 8.4.82 Get ASIC Temperature Response (0xA4)

The Package shall, in the absence of a checksum error or identifier mismatch, always accept the GetASIC Temperature Command and send a response.

- 2737 Table 151 illustrates the packet format of the Get ASIC Temperature Response.
- 2738

Table 151 – Get ASIC Temperature Response Packet

	Bits				
Bytes	3124	2316	1508	0700	
0015	NC-SI Header				
1619	Response Code Reason Code			n Code	
2023	Reserved	Reserved	Maximum temperature	Current temperature	
2427	Checksum (32) Checksum (10)				
3245	Pad				

2740 8.4.82.1 Maximum Temperature Value

This value is the maximum T-Diode temperature limit in degrees Celsius at which the controller can operate at full load for its rated service lifetime. The value should be derated to take measurement

tolerance into account. The value shall be reported as a hexadecimal integer number.

2744 8.4.82.2 Current Temperature Value

This value is the current real-time temperature of the chip in degrees Celsius. The value shall be reported as a hexadecimal integer number.

2747 8.4.83 Get Ambient Temperature (0x24)

- The Get Ambient Temperature command allows the Management controller to query for temperature values from ambient temperature sensor(s) attached to the Controller.
- 2750 The Get Ambient Temperature command is defined as a package command.
- 2751 Controllers that do not support ambient temperature sensors should not implement this command.
- Table 152 illustrates the packet format of the Get Ambient Temperature Command.

2753

Table 152 – Get Ambient Temperature Command Packet

	Bits					
Bytes	3124 2316 1508 0700					
0015	NC-SI Header					
1619	Reserved

2427	Checksum (32) Checksum (10)			
3245	Pad			

2761 **8.4.84.1 Temperature Value**

This value (zero or more as specified by the Number of sensors field) is the real time ambient temperature reported in degrees Celsius. The value shall be reported as a hexadecimal integer number.

2764 8.4.85 Get SFF Module Temperature (0x25)

The Get SFF Module Temperature command allows the Management controller to query for the real time temperature value and thresholds of the (optical) transceiver attached to the channel. Implementations that do not support either fixed optics or an SFF-like cage that supports pluggable transceivers that can provide temperature information, such as a Base-T Ethernet adapter, should not implement this command.

- 2770 Table 154 illustrates the packet format of the Get SFF Module Temperature Command.
- 2771

 Table 154 – Get SFF Module Temperature Command Packet

	Bits					
Bytes	3124 2316 1508 0700

2445	Pad					

2772

2773 8.4.86 Get SFF Module Temperature Response (0xA5)

The channel shall, in the absence of a checksum error or identifier mismatch, always accept the Get SFF Module Temperature command and send a response.

2776 The Get SFF Module Temperature Response frame contains the currently stored settings for the

2777 Definitions and interpretation of the data fields in the response are defined in the relevant SFF or MSA 2778 specification (e.g., SFF-8472, SFF-8436, SFF-8636, etc.) for the transceiver. 16 bit values are encoded 2779 as one contiguous entity with the most significant bit in bit 15 (or 31) and least significant bit in bit 0 (or 2780 16) in the response packet. The Controller is not expected to modify the data read from the transceiver.

In cases where the transceiver supports more than one channel, each channel shall provide a responsewhen queried.

The reason code - *Information not available* - shall be used if the transceiver is not present, does not
provide temperature data or if the command is issued before the transceiver has not yet achieved power
up state.

2786 Table 155 illustrates the packet format of the Get SFF Module Temperature Response.

2788

2787

2789 **8.4.87 OEM command (0x50)**

The OEM command may be used by the Management Controller to request that the channel provide vendor-specific information. The <u>Vendor Enterprise Number</u> is the unique MIB/SNMP Private Enterprise number assigned by IANA per organization. Vendors are free to define their own internal data structures in the vendor data fields.

Table 156 illustrates the packet format of the OEM command.

2795

Table 156 – OEM command packet format

20	PLDM Message Payload (zero or more bytes) + Payload Pad (see 8.2.2.2)				
	Checksum				
	E	Ethernet Packet Pad (optional – See 8.2.2.4)	

2807 Refer to the PLDM Base specification (DSP0240) for details on the PLDM Request Messages.

2808 8.4.90 PLDM Response (0xD1)

2809 The PLDM Response Message may be used by the Network Controller to send PLDM responses over

2810 NC-SI/RBT. The package shall, in the absence of a checksum error or identifier mismatch, always accept 2811 the PLDM Request Command and send a response.

2812

Table 159 – PLDM Response packet format

	Bits				
Bytes	3124	2316	1508	0700	
0015	NC-SI Control Message Header				
1619	Response Code Reason Code				
2023	PLDM Message Common Fields			PLDM Completion Code	

_	Bits				
Bytes	3124	2316	1508	0700	
24	PLDM Message Payload (zero or more bytes) + Payload Pad (see 8.2.2.2)				
	Checksum				
	Ethernet Packet Pad (optional – See 8.2.2.4)				

2813 Refer to the PLDM Base specification (DSP0240) for details on the PLDM Response Messages.

2814 Note the NC-SI PLDM Response (0xD1) response/reason codes are only used to report the support,

2815 success, or failure of the PLDM Request command (0x51) at the NC-SI over RBT messaging layer. The

PLDM Completion Code is used for determining the success or failure of the encapsulated PLDM 2816 2817

Commands at the PLDM messaging layer.

8.4.91 Query Pending NC PLDM Request (0x56) 2818

2819 The Query Pending NC PLDM Request may be used by the Management Controller to read the status of pending PLDM commands which the NC needs to send to the MC. Only one PLDM request can be 2820 handled at any time. When multiple requests are pending in the NC, each will be handled independently 2821 2822 and the order at which requests are provided to the MC is decided by the NC.

NC which supports PLDM over RBT, where the NC has to send PLDM commands to the MC, shall 2823 support this command. It is expected that the MC will use PLDM Request command 0x51 to query the 2824 supported PLDM commands, before using Query Pending NC PLDM Request command. 2825

2826

Table 160 – Query Pending NC PLDM Request Packet Format

2833 8.4.93 Send NC PLDM Reply (0x57)

The Reply Pending PLDM command may be used by the Management Controller to provide the PLDM command response to previously read PLDM command from the NC that requires a response (Rq = 1, D = 0 in PLDM Message Common Fields). The response to this command further provides indication to the MC regarding additional pending PLDM NC commands.

2838

2845

8.4.95 Pending PLDM request AEN and associated enablement commands 2846

- 2847 An optional medium specific AEN is defined. This AEN allows the NC to notify the MC regarding a pending PLDM command that the NC has to send to the MC. 2848
- 2849 As a transport specific AEN, this AEN is enabled using the transport specific AEN enable command, and 2850 is controlled by bit 1 in Transport Specific AENs enable field.
- 2851 The AEN Type for this AEN shall be 0×71 and is described below.

8.4.96 Transport Specific AEN Enable Command (0x55) 2852

2853 Network Controller implementations shall support this command on the condition that the Network Controller generates one or more transport specific AENs defined in this specification or other NC-SI 2854 bindings such as DSP0261. The AEN Enable command enables and disables the different transport 2855 specific AENs supported by the Network Controller. The Network Controller shall copy the AEN MC ID 2856 field from the AEN Enable command into the MC ID field in every subsequent AEN sent to the 2857 Management Controller as defined in AEN Enable command 2858

- 2859 Table 166 illustrates the packet format of the Enable Transport Specific AENs command.

2867

2868 8.4.98 Pending PLDM Request AEN

The Pending PLDM Request AEN is used to alert the MC that there is a pending PLDM request for the MC in the NC. This AEN allows for the MC to poll for pending PLDM request on the NC at a lower rate.

2871 This AEN should be sent if there is a new pending PLDM command that is available in the NC designated

to the MC, which was not reported to the MC through Send NC PLDM Reply Response (0xD7). A

2873 Pending PLDM Request AEN should not be sent from the time the NC recognizes an incoming Query

2874 Pending NC PLDM Request (0x56) until the NC sends Send NC PLDM Reply Response (0xD7) for 2875 the PLDM request.

2075 the PLDivi reques

2877 8.4.99 Get MC MAC Address command (0x53)

A network controller may provision MAC addresses for Out-Of-Band (OOB) management traffic. These
 MAC addresses are not visible to the host(s). Get MC MAC Address is used to discover MAC addresses
 provisioned on the network controller for the MC. Get MC MAC Address is a channel-specific command.
 For multi-port devices, it is expected that the MC queries provisioned MC MAC Addresses on each
 channel individually.

2883 Table 170 illustrates the packet format of the Get MC Address Command over NC-SI/RBT.

2884

Table 170 – Get MC MAC Address command packet format

	Bits			
Bytes	3124	2316	1508	0700
0015	NC-SI Header			
1619	Checksum			
2045	Pad			

2885 8.4.100 Get MC MAC Address response (0xD3)

In the response of Get MC MAC Address command, the network controller provides the information about
the provisioned MAC addresses for the MC on that channel. The NC shall, in the absence of an error,
always accept the Get MC MAC Address command and send the response packet shown in Table 171.
Currently no command-specific reason code is identified for this response.

2890

Table 171 – Get MC MAC Address response packet format

	Bits			
Bytes	3124	2316	1508	0700
0015	NC-SI Header			
1619	Respon	se Code	Reason Code	
2023	Address Count		Reserved	
	Addr 1 Byte 5	Addr 1 Byte 4 Addr 1 Byte 3		Addr 1 Byte 2
Variable	Addr 1 Byte 1	Addr 1 Byte 0 Addr 2 Byte 5 Addr 2 Byt		
variable				
		Pad (if needed)		needed)

2891 8.4.100.1 Address Count

2892 This field shall be set to the number of MC MAC addresses provisioned on the channel.

2893 **8.4.100.2 Reserved**

2894 This field shall be set to 0 by the network controller and shall be ignored by the management controller.

2895 8.4.100.3 Addr i Byte j

2896 This field shall be set to the value of jth byte $(1 \le j \le 6)$ of ith provisioned MC MAC address.

2897 8.4.100.4 Pad

2898 If the number of MC MAC addresses is an odd number, then 2 bytes of the Pad field shall be present at 2899 the end of the payload to align the payload on a 32-bit boundary. If present, each byte of the Pad field 2900 shall be set to 0×00 .

2901 If the number of MC MAC addresses is an even number, then 0 bytes of Pad shall be present.

2902 8.4.101 Get Package UUID command (0x52)

The Get Package UUID command may be used by the Management Controller to query Universally Unique Identifier (UUID), also referred to as a globally unique ID (GUID), of the Network Controller over NC-SI/RBT. This command is targeted at the entire package. This command can be used by the MC to correlate endpoints used on different NC-SI transports (e.g., RBT, MCTP).

2907 Table 172 illustrates the packet format of the Get Package UUID Command over NC-SI/RBT.

2908

Table 172 – Get Package UUID command packet format

	Bits			
Bytes	3124	2316	1508	0700
0015	NC-SI Control Message Header			
1619	Checksum			
2045		Pad		

2909 8.4.102 Get Package UUID response (0xD2)

The package shall, in the absence of an error, always accept the Get Package UUID command and send the response packet shown in Table 173. Currently no command-specific reason code is identified for this response.

2913

Table 173 – Get Package UUID response packet format

	Bits				
Bytes	3124	2316	1508	0700

2035	UUID bytes 1:16, respectively				
3639	Checksum				
4045	Pad				

2914 The individual fields within the UUID are stored most-significant byte (MSB) first per the convention

2915 described in RFC4122. RFC4122 specifies four different versions of UUID formats and generation

algorithms suitable for use for a UUID. These are version 1 (0001b) "time based", and three "name-

based" versions: version 3 (0011b) "MD5 hash", version 4 (0100b) "Pseudo-random", and version 5
"SHA1 hash". The version 1 format is recommended. However, versions 3, 4, or 5 formats are also
allowed. See Table 174 for the UUID format version 1.

2921

Field	UUID Byte	MSB
time low	1	MSB

	13	
	14	
	15	
	16	

2922 8.5 AEN packet formats

This clause defines the formats for the different types of AEN packets. For a list of the AEN types, see Table 16.

2925 8.5.1 Link Status Change AEN

The Link Status Change AEN indicates to the Management Controller any changes in the channel's external interface link status.

This AEN should be sent if any change occurred in the link status (that is, the actual link mode was changed). The Link Status and OEM Link Status fields reproduce the bit definitions defined in the Get Link Status Response Packet (see Table 48).

Network Controller Sideband Interface (NC-SI) Specification

2931 Table 175 illustrates the packet format of the Link Status Change AEN.

2932

2023	Link Status			
24.27	OEM Link Status			
2831	Checksum			

2933 8.5.2 Configuration Required AEN

The Configuration Required AEN indicates to the Management Controller that the channel is transitioning
 into the Initial State. (This AEN is not sent if the channel enters the Initial State because of a Reset
 Channel command.)

- 2937NOTEThis AEN may not be generated in some situations in which the channel goes into the Initial State. For
example, some types of hardware resets may not accommodate generating the AEN.
- 2939 Table 176 illustrates the packet format of the Configuration Required AEN.

Network Controller Sideband Interface (NC-SI) Specification

2945 The Host Network Controller Driver Status field has the format shown in Table 178.

2946

Table 178 – Host Network Controller Driver Status format

Bit Position	Name	Description
0	Host Network Controller Driver Status	0b = The Network Controller driver for the host external network interface associated with this channel is not operational (not running).
		1b = The Network Controller driver for the host external network interface associated with this channel is being reported as operational (running).
131	Reserved	Reserved

2947 8.5.4 Delayed Response Ready AEN

This AEN indicates the response to a delayed command is ready. Table 179 illustrates the packet format of the AEN.

2950

Table 179 – Delayed Response Ready AEN packet format

	Bits				
Bytes	3124	2316	1508	0700	
0015	AEN Header				
1619	Reserved AEN Type = 0x03

2427	Checksum				

The Original Command Type includes the Control Packet Type field of the completed command and the Original Command IID includes the IID field of the original command.

2953 9 Packet-based and op-code timing

Table 180 presents the timing specifications for a variety of packet-to-electrical-buffer interactions, interpacket timings, and op-code processing requirements. The following timing parameters shall apply to NC-SI over RBT binding defined in this specification.

Table 180 – NC-SI packet-based and op-code timing parameters

Name	Symbol	Value	Description
Package Deselect to Hi-Z Interval	Τ1	200 μs, max	Maximum time interval from when a Network Controller completes transmitting the response to a Deselect Package command to when the Network Controller outputs are in the high-impedance state
			Measured from the rising edge of the first clock that follows the last bit of the packet to when the output is in the high-impedance state as defined in clause 10
Package Output to Data	Τ2	2 clocks, min	Minimum time interval after powering up the output drivers before a Network Controller starts transmitting a packet through the NC-SI interface Measured from the rising edge of the first clock of the packet
Network Controller Power Up Ready Interval	T4	2 s, max	Time interval from when the NC-SI on a Network Controller is powered up to when the Network Controller is able to respond to commands over the NC-SI
			Measured from when V_{ref} becomes available
Normal Execution Interval	Т5	50 ms, max	Maximum time interval from when a controller receives a command to when it delivers a response to that command, unless otherwise specified
			Measured from the rising edge of the first clock following the last bit of the command packet to the rising edge of the clock for the first bit of the response packet
Asynchronous Reset Interval	Т6	2 s, max	Interval during which a controller is allowed to not recognize or respond to commands due to an Asynchronous Reset event
			For a Management Controller, this means that a Network Controller could become unresponsive for up to T6 seconds if an Asynchronous Reset event occurs. This is not an error condition. The Management Controller retry behavior should be designed to accommodate this possibility.
Synchronous Reset Interval	T7	2 s, max	Interval during which a controller may not recognize or respond to requests due to a Synchronous Reset event
			Measured from the rising edge of the first clock following the last bit of the Reset Channel response packet
Token Timeout	Т8	32,000 REF_CLK min	Number of REF_CLKs before timing out while waiting for a TOKEN to be received

²⁹⁵⁷

Name	Symbol	Value	Description
Op-Code Processing	Т9	32 REF_CLK max	Number of REF_CLKs after receiving an op-code on ARB_IN to decode the op-code and generate the next op-code on ARB_OUT
			Measured from the falling edge of the last bit of the op- code received on ARB_IN to the rising edge of the next op-code on ARB_OUT
Op-Code Bypass Delay	T10	32 REF_CLK max	Number of REF_CLK delays between a bit received on ARB_IN and the corresponding bit passed on to ARB_OUT while in Bypass Mode
			Measured from the falling edge of the last bit of the op- code received on ARB_IN to the rising edge of the next op-code on ARB_OUT
TOKEN to RXD	T11	T2 min, 32 REF_CLK	Number of REF_CLKs after receiving TOKEN to when packet data is driven onto the RXD lines
		max	Measured from the falling edge of the last bit of the op- code received on ARB_IN to the rising edge of the next op-code on ARB_OUT
Interval R		50,331,648 REF_CLK max	Maximum time period (3 XOFF Frame timer cycles) during which a channel within a package is allowed to request and renew a single XOFF condition after requesting the initial XOFF
IPG to TOKEN Op-code Overlap	T13	6 REF_CLK max	Maximum number of REF_CLKs that the beginning of TOKEN transmission can precede the end of the Inter Packet Gap. For more information, see 7.2.8.
Delayed Execution Interval	cution T14	4 s, max	Maximum time interval from when a controller receives a command to when it delivers a response to that command, including all responses with "Delayed Response" code
			Measured from the rising edge of the first clock following the last bit of the command packet to the rising edge of the clock for "Delayed Response Ready" AEN if enabled or to the moment the NC is internally ready with a response for a polling command.

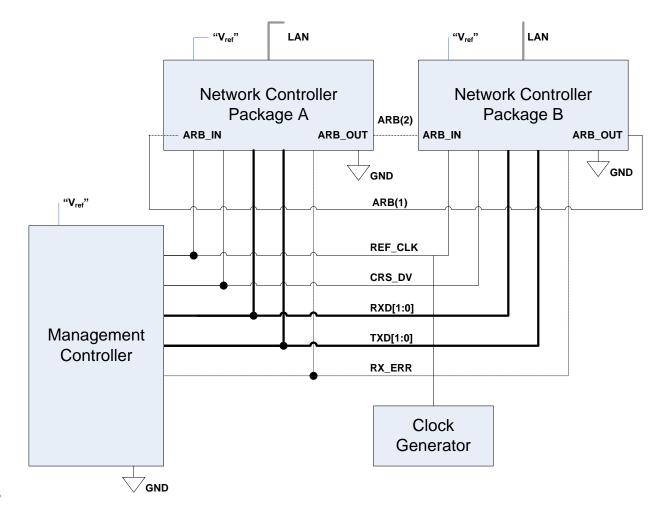

2958 **10 RBT Electrical specification**

This clause provides background information about the NC-SI specification, describes the NC-SI
 topology, and defines the electrical, timing, signal behavior, and power-up characteristics for the NC-SI
 physical interface.

2962 **10.1 Topologies**

2963 The electrical specification defines the NC-SI electrical characteristics for one management processor 2964 and one to four Network Controller packages in a bussed "multi-drop" arrangement. The actual number of 2965 devices that can be supported may differ based on the trace characteristics and routing used to 2966 interconnect devices in an implementation.

2967 Figure 16 shows an example topology.

2969

Figure 16 – Example NC-SI signal interconnect topology

2970 **10.2 Electrical and signal characteristics and requirements**

This clause defines the electrical, timing, signal behavior, and power-up characteristics for the NC-SI physical interface.

2973 **10.2.1 Companion specifications**

Implementations of the physical interface and signaling for the NC-SI shall meet the specifications in <u>RMII</u>
 and <u>IEEE 802.3</u>, except where those requirements differ or are extended with specifications provided in
 this document, in which case the specifications in this document shall take precedence.

2977 **10.2.2 Full-duplex operation**

The NC-SI is specified only for full-duplex operation. Half-duplex operation is not covered by this specification.

2980 **10.2.3 Signals**

Table 181 lists the signals that make up the NC-SI physical interface.

2982 Unless otherwise specified, the high level of an NC-SI signal corresponds to its asserted state, and the

low level represents the de-asserted state. For data bits, the high level represents a binary '1' and the low level a binary '0'.

2985

Signal Name	Direction (with respect to the Network Controller)	Direction (with respect to the Management Controller MAC)	Use	Mandatory or Optional
REF_CLK ^[a]	Input	Input	Clock reference for receive, transmit, and control interface	Μ
CRS_DV ^[b]	Output	Input	Carrier Sense/Receive Data Valid	М
RXD[1:0]	Output	Input	Receive data	М
TX_EN	Input	Output	Transmit enable	М
TXD[1:0]	Input	Output	Transmit data	М
RX_ER	Output	Input	Receive error	0
ARB_IN	Input ^[c]	N/A	Network Controller hardware arbitration Input	O ^[c]
ARB_OUT	Output ^[c]	N/A	Network Controller hardware arbitration Output	O ^[c]

Table 181 – Physical NC-SI signals

^[a] A device may provide an additional option to allow it to be configured as the source of REF_CLK, in which case the device is not required to provide a separate REF_CLK input line, but it can use REF_CLK input pin as an output. The selected configuration shall be in effect at NC-SI power up and remain in effect while the NC-SI is powered up.

^[b] In the <u>RMII Specification</u>, the MII Carrier Sense signal, CRS, was combined with RX_DV to form the CRS_DV signal. When the NC-SI is using its specified full-duplex operation, the CRS aspect of the signal is not required; therefore, the signal shall provide only the functionality of RX_DV as defined in <u>IEEE 802.3</u>. (This is equivalent to the CRS_DV signal states in <u>RMII Specification</u> when a carrier is constantly present.) The Carrier Sense aspect of the CRS_DV signal is not typically applicable to the NC-SI because it does not typically detect an actual carrier (unlike an actual PHY). However, the Network Controller should emulate a carrier-present status on CRS_DV per <u>IEEE 802.3</u> in order to support Management Controller MACs that may require a carrier-present status for operation.

^[c] If hardware arbitration is implemented, the Network Controller package shall provide both ARB_IN and ARB_OUT connections. In some implementations, ARB_IN may be required to be tied to a logic high or low level if it is not used.

2986 **10.2.4 High-impedance control**

Shared NC-SI operation requires Network Controller devices to be able to set their NC-SI outputs
(RXD[1:0], CRS_DV, and, if implemented, RX_ER) into a high-impedance state either upon receipt of a
command received through NC-SI, or, if hardware-based arbitration is in effect, as a result of hardwarebased arbitration. A pull down resistor should be provided on high impedance lines in a way that will keep
the C_{load} value so that the line won't float.

Network Controller packages shall leave their NC-SI outputs in the high-impedance state on interface
 power up and shall not drive their NC-SI outputs until selected. For additional information about Network
 Controller packages, see 8.4.5.

Network Controller Sideband Interface (NC-SI) Specification

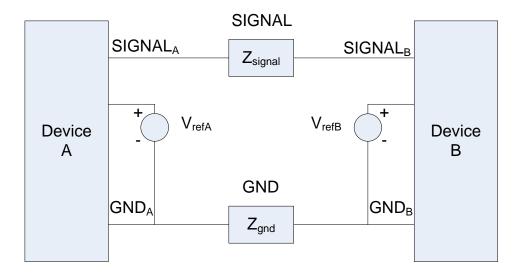

For NC-SI output signals in this specification, unless otherwise specified, the high-impedance state is defined as the state in which the signal leakage meets the I_z specification provided in 10.2.5.

2997 10.2.5 DC characteristics

2998 This clause defines the DC characteristics of the NC-SI physical interface.

2999 **10.2.5.1 Signal levels**

- 3000 CMOS 3.3 V signal levels are used for this specification.
- 3001 The following characteristics apply to DC signals:
- Unless otherwise specified, DC signal levels and V_{ref} are measured relative to Ground (GND) at the respective device providing the interface, as shown in Figure 17.
- Input specifications refer to the signals that a device shall accept for its input signals, as
 measured at the device.
- Output specifications refer to signal specifications that a device shall emit for its output signals, as measured at the device.

3008

- 3010 Table 182 provides DC specifications.
- 3011

Table	182 –	DC	specifications
-------	-------	----	----------------

Parameter	Symbol	Conditions	Minimum	Typical	Maximum	Units
IO reference voltage	V _{ref} ^[a]		3.0	3.3	3.6	V
Signal voltage range	V _{abs}		-0.300		3.765	V
Input low voltage	Vil				0.8	V
Input high voltage	V _{ih}		2.0			V
Input high current	l _{ih}	V _{in} = V _{ref} = V _{ref} ,max	0		200	μA
Input low current	lii	V _{in} = 0 V	-20		0	μA
Output low voltage	V _{ol}	$I_{ol} = 4 \text{ mA}, V_{ref} = \min$	0		400	mV
Output high voltage	V _{oh}	I_{oh} = -4 mA, V_{ref} = min	2.4		V _{ref}	V
Clock midpoint reference level	V _{ckm}				1.4	V
Leakage current for output signals in high-impedance state	lz	$\begin{array}{l} 0 \leq V_{in} \leq V_{ref} \\ at \; V_{ref} = V_{ref}, max \end{array}$	-20		20	μA

^{a]} V_{ref} = Bus high reference level (typically the NC-SI logic supply voltage). This parameter replaces the term *supply voltage* because actual devices may have internal mechanisms that determine the operating reference for the NC-SI that are different from the devices' overall power supply inputs.

 V_{ref} is a reference point that is used for measuring parameters (such as overshoot and undershoot) and for determining limits on signal levels that are generated by a device. In order to facilitate system implementations, a device shall provide a mechanism (for example, a power supply pin, internal programmable reference, or reference level pin) to allow V_{ref} to be set to within 20 mV of any point in the specified V_{ref} range. This approach enables a system integrator to establish an interoperable V_{ref} level for devices on the NC-SI.

3012 **10.2.6 AC characteristics**

3013 This clause defines the AC characteristics of the NC-SI physical interface.

3014 **10.2.6.1 Rise and fall time measurement**

3015 Rise and fall time are measured between points that cross 10% and 90% of V_{ref} (see Table 182). The 3016 middle points (50% of V_{ref}) are marked as V_{ckm} and V_m for clock and data, respectively.

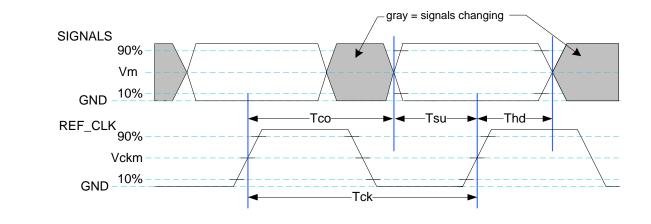

3017 **10.2.6.2 REF_CLK measuring points**

3018 In Figure 18, REF_CLK duty cycle measurements are made from V_{ckm} to V_{ckm} . Clock skew T_{skew} is 3019 measured from V_{ckm} to V_{ckm} of two NC-SI devices and represents maximum clock skew between any two 3020 devices in the system.

3021 **10.2.6.3 Data, control, and status signal measuring points**

3022 In Figure 18, all timing measurements are made between V_{ckm} and V_m . T_{co} is measured with a capacitive 3023 load between 10 pF and 50 pF. Propagation delay T_{prop} is measured from V_m on the transmitter to V_m on 3024 the receiver.

Network Controller Sideband Interface (NC-SI) Specification

3025

3026

Figure 18 – AC measurements

3027 Table 183 provides AC specifications.

3028

Table 183 – AC specifications

Parameter	Symbol	Minimum	Typical	Maximum	Units
REF_CLK Frequency			50	50+100 ppm	MHz
REF_CLK Duty Cycle		35		65	%
Clock-to-out ^[a] (10 pF $\leq c_{load} \leq 50$ pF)	T _{co}	2.5		12.5	ns
Skew between clocks	T _{skew}			1.5	ns
TXD[1:0], TX_EN, RXD[1:0], CRS_DV, RX_ER, and ARB_IN data setup to REF_CLK rising edge	T _{su}	3			ns
TXD[1:0], TX_EN, RXD[1:0], CRS_DV, RX_ER, and ARB_OUT data hold from REF_CLK rising edge	T_{hd}	1			ns
Signal Rise/Fall Time	T _r /T _f	0.5		6	ns
REF_CLK Rise/Fall Time	T _{ckr} /T _{ckf}	0.5		3.5	ns
Interface Power-Up High-Impedance Interval	T _{pwrz}	2			μs
Power Up Transient Interval (recommendation)	T _{pwrt}			100	ns
Power Up Transient Level (recommendation)	V _{pwrt}	-200		200	mV
EXT_CLK Startup Interval	T _{clkstrt}			100	ms

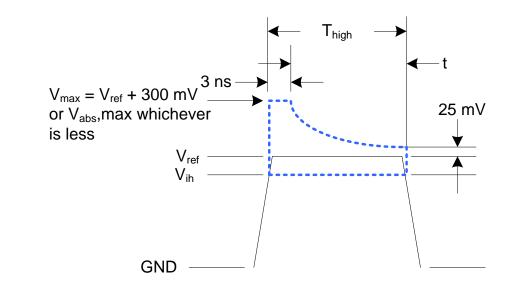

3029 **10.2.6.4 Timing calculation (informative)**

This clause presents the relationships between the timing parameters and how they are used to calculate setup and hold time margins.

- 3032 10.2.6.4.1 Setup calculation
- $T_{su} \leq T_{clk} (T_{skew} + T_{co} + T_{prop})$
- 3034 10.2.6.4.2 Hold calculation
- $T_{hd} \le T_{co} T_{skew} + T_{prop}$

3036 **10.2.6.5 Overshoot specification**

3037 Devices shall accept signal overshoot within the ranges specified in Figure 19, measured at the device,3038 without malfunctioning.

3039

3040

Figure 19 – Overshoot measurement

3041 The signal is allowed to overshoot up to the specified V_{max} for the first 3 ns following the transition above 3042 V_{ih} . Following that interval is an exponential decay envelope equal to the following:

3043
$$V_{ref} + V_{os} * e^{-[-K * ([t - 3 ns]/T_d)]}$$

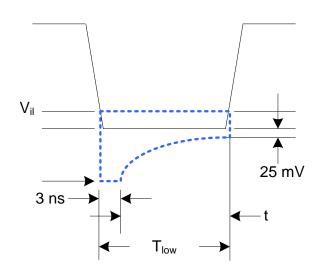

3044 Where, for t = 3 to 10 ns:

- t = 0 corresponds to the leading crossing of V_{ih}, going high.
- 3046 V_{ref} is the bus high reference voltage (see 10.2.5).
- 3047 V_{abs},max is the maximum allowed signal voltage level (see 10.2.5).
- $3048 \qquad \qquad V_{os} = V_{max} V_{ref}$

- 3049 $K = I_n(25 \text{ mV/V}_{os})$
- 3050 $T_d = 7 \text{ ns}$
- 3051 For t > 10 ns, the V_{ref} + 25 mV limit holds flat until the conclusion of T_{high} .

3052 10.2.6.6 Undershoot specification

3053 Devices are required to accept signal undershoot within the ranges specified in Figure 20, measured at 3054 the device, without malfunctioning.

3055

3056

Figure 20 – Undershoot measurement

3057 The signal is allowed to undershoot up to the specified V_{abs} ,min for the first 3 ns following the transition 3058 above V_{il} . Following that interval is an exponential envelope equal to the following:

3059 * ([t –3 ns]/T_d)]

3060 Where, for t = 3 to 10 ns:

- 3061 t = 0 corresponds to the leading crossing of V_{il}, going low.
- 3062 V_{abs}, min is the minimum allowed signal voltage level (see 10.2.5).
- 3063 $K = I_n(25 \text{ mV/V}_{os})$
- 3064 $T_d = 7 \text{ ns}$
- 3065 For t > 7 ns, the GND 25 mV limit holds flat until the conclusion of T_{low} .

3066 **10.2.7 Interface power-up**

To prevent signals from back-powering unpowered devices, it is necessary to specify a time interval
 during which signals are not to be driven until devices sharing the interface have had time to power up.
 To facilitate system implementation, the start of this interval shall be synchronized by an external signal
 across devices.

3071 10.2.7.1 Power-up control mechanisms

The device that provides the interface shall provide one or more of the following mechanisms to enable the system integrator to synchronize interface power-up among devices on the interface:

Device power supply pin

3075The device has a power supply pin that the system integrator can use to control power-up of the3076interface. The device shall hold its outputs in a high-impedance state (current < I_z) for at least3077 T_{pwrz} seconds after the power supply has initially reached its operating level (where the power3078supply operating level is specified by the device manufacturer).

Device reset pin or other similar signal

3080The device has a reset pin or other signal that the system integrator can use to control the3081power-up of the interface. This signal shall be able to be driven asserted during interface power-3082up and de-asserted afterward. The device shall hold its outputs in a high-impedance state3083(current < I_z) for at least T_{pwrz} seconds after the signal has been de-asserted, other than as3084described in 10.2.7.2. It is highly recommended that a single signal be used; however, an3085implementation is allowed to use a combination of signals if required. Logic levels for the signals3086are as specified by the device manufacturer.

3087 • REF_CLK detection

3088The device can elect to detect the presence of an active REF_CLK and use that for determining3089whether NC-SI power up has occurred. It is recommended that the device should count at least3090100 clocks and continue to hold its outputs in a high-impedance state (current < I_z) for at least3091T_{pwrz} seconds more (Informational: 100 clocks at 50 MHz is 2 us).

3092 **10.2.7.2 Power-up transients**

3093 It is possible that a device may briefly drive its outputs while the interface or device is first receiving
 3094 power, due to ramping of the power supply and design of its I/O buffers. It is recommended that devices
 3095 be designed so that such transients, if present, are less than V_{pwrt} and last for no more than T_{pwrt}.

3096 **10.2.8 REF_CLK startup**

REF_CLK shall start up, run, and meet all associated AC and DC specifications within T_{clkstrt} seconds of interface power up.

3099 3100	ANNEX A (normative)
3101	
3102	Extending the Model

3103 This annex explains how the model can be extended to include vendor-specific content.

3104 Commands extension

A Network Controller vendor may implement extensions and expose them using the OEM command, as described in 8.4.57.

3107 **Design considerations**

3108 This clause describes certain design considerations for vendors of Management Controllers.

3109 **PHY support**

3110 Although not a requirement of this specification, a Management Controller vendor may want to consider

3111 designing an NC-SI in such a manner that it could also be configured for use with a conventional RMII

3112 PHY. This would enable the vendor's controller to also be used in applications where a direct, non-shared

3113 network connection is available or preferred for manageability.

3114 Multiple Management Controllers support

3115 Currently, there is no requirement for Management Controllers to be able to put their TXD output lines 3116 and other output lines into a high-impedance state, because the present definition assumes only one Management Controller on the bus. However, component vendors may want to consider providing such 3117 3118 control capabilities in their devices to support possible future system topologies where more than one 3119 Management Controller shares the bus to enable functions such as Management Controller fail-over or to 3120 enable topologies where more than one Management Controller can do NC-SI communications on the 3121 bus. If a vendor elects to make such provision, it is recommended that the TXD line and the remaining 3122 output lines be independently and dynamically switched between a high-impedance state and re-enabled 3123 under firmware control.

3125		ANNEX B					
3126	(informative)						
3127							
3128	Relationship to RMII Specification						
2120	Difforo	neas with the DMII Specification					
3129		nces with the RMII Specification					
3130 3131		wing list presents key differences and clarifications between the <i>NC-SI Specification</i> and in the <i><u>RMII Specification</u>.</i> (Section numbers refer to the <u><i>RMII Specification</i></u> .)					
3132 3133	•	General: Where specifications from <u>IEEE 802.3</u> apply, this specification uses the version specified in clause 2, rather than the earlier IEEE 802.3u version that is referenced by <u>RMII</u> .					
3134	•	Section 1.0:					
3135 3136		 The NC-SI Specification requires 100 Mbps support, but it does not specify a required minimum. (10 Mbps support is not required by NC-SI.) 					
3137		 Item 4. (Signals may or may not be considered to be TTL. NC-SI is not 5-V tolerant.) 					
3138	•	Section 2.0:					
3139 3140		 Comment: NC-SI chip-to-chip includes considerations for multi-drop and allows for non- PCB implementations and connectors (that is, not strictly point-to-point). 					
3141	•	Section 3.0:					
3142 3143		 Note/Advisory: The NC-SI clock is provided externally. An implementation can have REF_CLK provided by one of the devices on the bus or by a separate device. 					
3144	•	Section 5.0:					
3145		- For NC-SI, the term <i>PHY</i> is replaced by <i>Network Controller</i> .					
3146	•	Table 1:					
3147 3148		 The information in Table 1 in the <u><i>RMII Specification</i></u> is superseded by tables in this specification. 					
3149	•	Section 5.1, paragraph 2:					
3150 3151		 The NC-SI Specification allows 100 ppm. This supersedes the <u>RMII Specification</u>, which allows 50 ppm. 					
3152	•	Section 5.1, paragraph 3:					
3153 3154		 The NC-SI inherits the same requirements. The NC-SI MTU is required only to support Ethernet MTU with VLAN, as defined in the <u>IEEE 802.3</u> version listed in clause 2. 					
3155	•	Section 5.1 paragraph 4:					
3156 3157 3158 3159 3160 3161 3162 3163		The <u>RMII Specification</u> states: "During a false carrier event, CRS_DV shall remain asserted for the duration of carrier activity." This statement is not applicable to full-duplex operation of the NC-SI. CRS_DV from the Network Controller is used only as a data valid (DV) signal. Because the Carrier Sense aspect of CRS_DV is not used for full-duplex operation of the NC-SI, the Network Controller would not generate false carrier events for the NC-SI. However, it is recommended that the MAC in the Management Controller be able to correctly detect and handle these patterns if they occur, as this would be part of enabling the Management Controller MAC to also be able to work with an RMII PHY.					

3164	٠	Section 5.2:
3165 3166		 The NC-SI does not specify a 10 Mbps mode. The Carrier Sense aspect of CRS_DV is not used for full-duplex operation of NC-SI.
3167	٠	Section 5.3.1:
3168 3169 3170 3171		 While the NC-SI does not specify Carrier Sense usage of CRS_DV, it is recommended that a Management Controller allow for CRS_DV toggling, in which CRS_DV toggles at 1/2 clock frequency, and that Management Controller MACs tolerate this and realign bit boundaries correctly in order to be able to work with an RMII PHY also.
3172	٠	Section 5.3.2:
3173		 There is no 10 Mbps mode specified for the NC-SI.
3174	٠	Section 5.3.3:
3175 3176 3177		 Generally there is no expectation that the Network Controller will generate these error conditions for the NC-SI; however, the MAC in the Management Controller should be able to correctly detect and handle these patterns if they occur.
3178	٠	Section 5.3.3:
3179		 The NC-SI does not specify or require support for RMII Registers.
3180	٠	Section 5.5.2:
3181 3182		 Ignore (N/A) text regarding 10 Mbps mode. The NC-SI does not specify or require interface operation in 10 Mbps mode.
3183	٠	Section 5.6:
3184 3185 3186 3187		 The Network Controller will not generate collision patterns for the specified full-duplex operation of the NC-SI; however, the MAC in the Management Controller should be able to detect and handle these patterns if they occur in order to be able to work with an RMII PHY also.
3188	٠	Section 5.7:
3189		 NC-SI uses the <u>IEEE 802.3</u> version listed in clause 2 instead of 802.3u as a reference.
3190	٠	Section 5.8:
3191		 Loopback operation is not specified for the NC-SI.
3192	٠	Section 7.0:
3193 3194 3195		 The NC-SI electrical specifications (clause 10) take precedence. (For example, section 7.4.1 in the <u>RMII Specification</u> for capacitance is superseded by NC-SI Specification 25 pF and 50 pF target specifications.)
3196	٠	Section 8.0:
3197		 NC-SI uses the <u>IEEE 802.3</u> version listed in clause 2 as a reference, instead of 802.3u.
